Appendix E ECOTOX Bibliography

PHOSMET/PHOSMET OXON
Papers that Were Accepted for ECOTOX

Acceptable for ECOTOX and OPP

1. Ahmad, M., Hollingworth, R. M., and Wise, J. C. (2002). Broad-Spectrum Insecticide Resistance in Obliquebanded Leafroller _Choristoneura rosaceana_ (Lepidoptera: Tortricidae) from Michigan. *Pest Manag.Sci.* 58: 834-838.

   EcoReference No.: 70966
   Chemical of Concern: IDC,CFP,EMMB,MFZ,TUZ,BFT,ZCYP,AZ,CPY,PSM,CYP,DM,EFV,FNV,ES,TDC,MOM,CBL,SS; Habitat: T; Effect Codes: MOR; Rejection Code: LITE EVAL CODED(AZ,IDC,CFP,EMMB,MFZ,TUZ,BFT,ZCYP,CPY,PSM,CYP,DM,EFV,FNV,ES,TDC,MOM,CBL,SS).

2. Brunner, J. F., Dunley, J. E., Doerr, M. D., and Beers, E. H. (2001). Effect of Pesticides on Colpoclypeus florus (Hymenoptera: Eulophidae) and Trichogramma platneri (Hymenoptera: Trichogrammatidae), Parasitoids of Leafrollers in Washington. *J.Econ.Entomol.* 94: 1075-1084.

   EcoReference No.: 63713
   Chemical of Concern: AZ,DZ,DMT,MP,MDT,PSM,OML,CBL,FTT,AMZ,PMR,ES,EFV,IMC,SS,PPG,DFZ,FYC,TUZ,MFZ,AZD,CPY,PSM; Habitat: T; Effect Codes: MOR,BEH,REP; Rejection Code: LITE EVAL CODED(MP,AZ,DZ,CPY,DMT,MDT,PSM,OML,CBL,FTT,AMZ,PMR,ES,EFV,IMC,SS,PPG,DFZ,FYC,TUZ,MFZ,AZD),TARGET(CBL).

3. Burgess, N. M., Hunt, K. A., Bishop, C., and Weseloh, D. V. (1999). Cholinesterase Inhibition in Tree Swallows (Tachycineta bicolor) and Eastern Bluebirds (Sialia sialis) Exposed to Organophosphorus Insecticides in Apple Orchards in Ontario, Canada. *Environ.Toxicol.Chem.* 18 : 708-716.

   EcoReference No.: 47897
   Chemical of Concern: PHSL,PSM,AZ,DZ; Habitat: T; Effect Codes: BCM; Rejection Code: LITE EVAL CODED(DZ,PSM),OK(AZ).

4. DeVaney, J. A. and Ivie, G. W. (1980). Systemic Activity of Coumaphos, Famphur, Crufomate, Ronnel, and Phosmet Given Orally to Hens for Control of the Northern Fowl Mite, Ornithonyssus sylviarum (Canestrini and Fanzago). *Poult Sci* 59: 1208-1210.

   EcoReference No.: 48673
   Chemical of Concern: PSM,CMPH; Habitat: T; Effect Codes: POP,GRO,BEH; Rejection Code: LITE EVAL CODED(PSM).

5. Doerr, M. D., Brunner, J. F., and Schrader, L. E. (2004). Integrated Pest Management Approach for a New Pest, Lacanobia subjuncta (Lepidoptera: Noctuidae), in Washington Apple Orchards. *Pest Manag.Sci.* 60: 1025-1034.

   EcoReference No.: 82540
   Chemical of Concern: EMMB,MFZ,TUZ,CBL,TDC,MOM,ES,TMX,ACT,TAP,SS,AZD,AZ,CPY,PSM,MLN,IDC,EFV,KLN; Habitat: T; Effect Codes: MOR; Rejection Code: LITE EVAL CODED(ALL CHEMS),LITE

EVAL CODED(CPY).

6. Hagley, E. A. C. (1983). Pesticides, Pollination, and Fruit Set on Apple. *Can.Entomol.* 115: 1535-1536.

EcoReference No.: 36954
Chemical of Concern: AZ,PMR,PHSL,PSM; Habitat: T; Effect Codes: POP,BEH,REP,GRO; Rejection Code: LITE EVAL CODED(PSM,PMR),OK(AZ).

7. Haley, T. J., Farmer, J. H., Harmon, J. R., and Dooley, K. L. (1975). Estimation of the LD1 and Extrapolation of the LD0.1 for Five Organothiophosphate Pesticides. *Eur.J.Toxicol.* 8: 229-235.

EcoReference No.: 61388
Chemical of Concern: FNT,AZ,MP,PRN,PSM; Habitat: T; Effect Codes: PHY,MOR; Rejection Code: LITE EVAL CODED(PSM),OK(AZ,MP).

8. Harris, C. R. and Svec, H. J. (1970). Laboratory Studies on the Contact Toxicity of Some Insecticides to Honeybees. *Proc.Entomol.Soc.Ont.* 100: 165-167.

EcoReference No.: 96694
Chemical of Concern: ES,MXC,PSM,MLN,DZ,MOM,CBF,PRN,Naled,AZ,DMT,CBL,DLD; Habitat: T; Effect Codes: MOR; Rejection Code: LITE EVAL CODED(PSM),OK(MLN,DZ,MOM,CBF,Naled,AZ,DMT,CBL).

9. Heath, R. G., Spann, J. W., Hill, E. F., and Kreitzer, J. F. (1972). Comparative Dietary Toxicities of Pesticides to Birds. *U.S.Bureau of Sport Fisheries and Wildlife.Special Scientific Report-Wildlife No.152* 57 p.

EcoReference No.: 35214
Chemical of Concern: ABT,AND,AMTL,ATZ,PPX,Captan,CHL,CHD,TCF,24DXY,DDT,24DB,DDVP,DEM,DEZ,DBN,DCF,DLD,DS,CU,CPY,DMT,SZ,FNF,ES,EN,TXP,FNT,FNTH,AZ,HPT,PSM,HCCH,MLN,MCPB,MTAS,MOM,MXC,MP,MRX,Nabam,Naled,OXC,PRN,PCP,PRT,PPHD,PCL,TFM,THM; Habitat: T; Effect Codes: MOR; Rejection Code: LITE EVAL CODED(PSM,DS,CBL,DZ,ATZ,SZ,DMT,MLN,MP,Captan,Naled).

10. Hill, E. F. and Camardese, M. B. (1986). Lethal Dietary Toxicities of Environmental Contaminants and Pesticides to Coturnix. *U.S.Fish Wildl.Serv., Fish Wildl.Tech.Rep.No.2* 147 p.

EcoReference No.: 50181
Chemical of Concern: PSM,PRT,ADC,PMR,PRN,PAQT,ACP,Naled,MLN,HCCH,HPT,FNF,EN,ES,TMP,MTAS,MTM,MOM,AND,ATZ,BMY,DCTP,CBL,Captan,CPY,TBO,DZ,DLD,DU,FNTH,AZ,SZ,CPYM; Habitat: T; Effect Codes: MOR,BEH; Rejection Code: LITE EVAL CODED(ADC,ACP,MLN,MTAS,MTM,MOM,CBL,Captan,DZ,SZ,ATZ,MP,Naled,CPY,MLT,CBF,CPYM,PSM),OK(ALL CHEMS),NO COC(BMC).

11. Hill, E. F., Heath, R. G., Spann, J. W., and Williams, J. D. (1975). Lethal Dietary Toxicities of Environmental Pollutants to Birds. *U.S.Fish and Wildl.Serv.No.191, Special Scientific Report-Wildlife* 1-61.

EcoReference No.: 35243
Chemical of Concern: 24DXY,ABT,ADC,AMTL,AND,ATZ,Captan,CBF,CBL,Cd,Cr,DDT,DLD,DMT,DS,DU,DZ,ES,ETN,FNT,HCCH,Hg,HPT,MCPB,MLN,MP,MRX,MTAS,MXC,Naled,Pb,PCB,PCL,PCP,PQT,PRN,PRT,PYN,RSM,RTN,SZ,TFM,THM,TVP,TXP,Zn,ZnP,As,AZ,OXD,PSM,LNR; Habitat: T; Effect Codes: MOR; Rejection Code: LITE EVAL CODED(LNR,PSM,DS,24DXY,CPY,MP,Naled,Captan,MLN,OXD,MTAS,CBL,DZ,ATZ,CBF,ADC,MOM,DMT,SZ,ZnP,RTN,RSM,MCPB,PCP,PRT),OK(ALL CHEMS).

12. Hoffman, D. J. and Albers, P. H. (1984). Evaluation of Potential Embryotoxicity and Teratogenicity of 42 Herbicides, Insecticides, and Petroleum Contaminants to Mallard Eggs. *Arch.Environ.Contam.Toxicol.* 13: 15-27.

EcoReference No.: 35249
Chemical of Concern: ACP,CBL,DZ,DMT,EN,HCCH,MLN,MOM,Naled,PRN,PMR,PSM,SPS,TMP,TXP,AMTL,ATZ,BMN,MCPA,24DXY,DMB,GYP,PAQT,PCL,PRO,PPN,TFN,ALSV; Habitat: T; Effect Codes: MOR,GRO; Rejection Code: LITE EVAL CODED(PSM,24DXY,Naled,MLN,CBL,ACP,PRO,DZ,ATZ,MOM,DMT,DMB,ALSV),OK(ALL CHEMS),NO MIXTURE(BMN,MCPA).

13. Hudson, R. H., Tucker, R. K., and Haegele, M. A. (1984). Handbook of Toxicity of Pesticides to Wildlife. *Resour.Publ.No.153, Fish Wildl.Serv., 2nd Edition, U.S.D.I., Washington, DC* 90 p.

EcoReference No.: 50386
Chemical of Concern: ACP,ACL,ACR,ADC,AND,ATN,AMTL,ANZ,ATZ,4AP,AZ,PPX,BTY,Captan,CBL,CBF,CHD,CQTC,CPY,CMPH,CZE,24D,DDT,DDVP,DEF,DEM,DZ,DBN,DLN,DCF,DCTP,DLD,DMT,DQTBr,DS,DU,ES,EDT,EN,EP,ETN,FNT,FNTH,FMV,Folpet,FNF,HPT,PSM,HCCH,MLN,MDT,MCB,MOM,MTPN,MXC,MP,MVP,MRX,NABAM,Naled,FMP,PQT,PRN,PCP,PRT,PCL,RSM,RTN,STAR,STCH,TCDD,TMP,TZL,TVP,TZL,THM,TXP,TCF,TFN,ZnP,Zineb,PCB; Habitat: T; Effect Codes: MOR; Rejection Code: LITE EVAL CODED(PSM,ATZ,DU,MDT,PRT,RTN,CPY,24D,DS).

14. Johnson, J. C. Jr. and Bowman, M. C. (1968). Fate of Bidrin and Imidan when Fed in Silage to Lactating Dairy Cows. *J.Dairy Sci.* 51: 1225-1228.

EcoReference No.: 37334
Chemical of Concern: PSM,DCTP; Habitat: T; Effect Codes: BEH,PHY,BCM,ACC; Rejection Code: LITE EVAL CODED(PSM).

15. Johnson, J. C. Jr., Lowrey, R. S., Bowman, M. C., Leuck, D. B., Beck, E. W., and Derbyshire, J. C. (1968). Responses from Cows Fed Silages Containing Imidan Residues. *J.Dairy Sci.* 51: 1219-1224.

EcoReference No.: 37338
Chemical of Concern: PSM; Habitat: T; Effect Codes: PHY,ACC,BCM,REP; Rejection Code: LITE EVAL CODED(PSM).

16. Julin, A. M. and Sanders, H. O. (1977). Toxicity and Accumulation of the Insecticide Imidan in Freshwater Invertebrates and Fishes. *Trans.Am.Fish.Soc.* 106: 386-392 (Publ in Part As 6797).

EcoReference No.: 857
Chemical of Concern: PSM; Habitat: A; Effect Codes: ACC,MOR,PHY; Rejection Code: LITE EVAL CODED(PSM).

17. Martson, L. V. and Voronina, V. M. (1976). Experimental Study of the Effect of a Series of Phosphoroorganic Pesticides (Dipterex and Imidan) on Embryogenesis. *Environ.Health Perspect.* 13: 121-125.

EcoReference No.: 94874
Chemical of Concern: TCF,PSM; Habitat: T; Effect Codes: REP,MOR,PHY; Rejection Code: LITE EVAL CODED(PSM).

18. Mayer, D. F., Lunden, J. D., and Kovacs, G. (1997). Susceptibility of Four Bee Species (Hymenoptera: Apoidea) to Field Weathered Insecticide Residues. *J.Entomol.Soc.B.C.* 94: 27-30.

EcoReference No.: 91624

Chemical of Concern: MDT,OMC,TDC,CYP,CBF,DM,MTM,MP,PMR,PSM,PRB,TCF; Habitat: T; Effect Codes: MOR; Rejection Code: LITE EVAL CODED(MP,MDT,DMC,PMR,PSM),OK(MTM).

19. McLeod, M. J., Twidwell, E. K., and Gallenberg, D. J. (1994). Alfalfa Weevil Control, 1993. *Arthropod Manag.Tests* 19: 172-173 (No. 7F).

EcoReference No.: 88952
Chemical of Concern: CPY,CBF,PSM,MP,MLN,CBL,PMR; Habitat: T; Effect Codes: POP,BCM; Rejection Code: LITE EVAL CODED(CPY,CBL,MLN,PSM,PMR),OK(CBF,MP).

20. Mount, M. E. (1984). Comparison of Measurement of Dialkyl Phosphates in Milk/Urine and Blood Cholinesterase and Insecticide Concentrations in Goats Exposed to the Organophosphate Insecticide, Imidan. *Toxicol.Appl.Pharmacol.* 72: 236-244.

EcoReference No.: 38047
Chemical of Concern: PSM; Habitat: T; Effect Codes: ACC,BCM,CEL,PHY; Rejection Code: LITE EVAL CODED(PSM).

21. Serrano, R., Hernandez, F., Pena, J. B., Dosda, V., and Canales, J. (1995). Toxicity of Bioconcentration of Selected Organophosphorus Pesticides in Mytilus galloprovincialis and Venus gallina. *Arch.Environ.Contam.Toxicol.* 29: 284-290.

EcoReference No.: 14927
Chemical of Concern: CPY,DMT,MDT,PSM; Habitat: A; Effect Codes: ACC,MOR,BEH; Rejection Code: LITE EVAL CODED(PSM,CPY,DMT),OK(ALL CHEMS).

22. Shellenberger, T. E., Gough, B. J., and Escuriex, L. A. (1970). The Comparative Toxicity of Organophosphate Pesticides in Wildlife. *In: W.B.Deichmann, (Ed.), Pesticides Symposia, Inter-Am.Conf.Toxicol.Occup.Med., Univ.of Miami Schl.of Med., Miami, FL* 205-210.

EcoReference No.: 73198
Chemical of Concern: FNT,PSM,PRN,MP,AZ,DCTP; Habitat: T; Effect Codes: REP,MOR,BCM; Rejection Code: LITE EVAL CODED(MP,PSM),OK(AZ).

23. Sherman, M., Herrick, R. B., Chang, M. T. Y., and Menn, J. J. (1967). Comparative Toxicity of Imidan and Homologs Containing Asymmetrical Esters to the Chick, Rat, and House Fly. *J.Med.Entomol.* 4: 451-455.

EcoReference No.: 96637
Chemical of Concern: PSM; Habitat: T; Effect Codes: MOR,GRO; Rejection Code: LITE EVAL CODED(PSM).

24. Sherman, M., Ross, E., and Chang, M. T. Y. (1964). Acute and Subacute Toxicity of Several Organophosphorus Insecticides to Chicks. *Toxicol.Appl.Pharmacol.* 6: 147-153.

EcoReference No.: 38751
Chemical of Concern: PSM,OXD; Habitat: T; Effect Codes: GRO,MOR,PHY,BCM; Rejection Code: LITE EVAL CODED(PSM),OK(OXD).

25. Sherman, M. and Sanchez, F. F. (1968). Further Studies on the Toxicity of Insecticides and Acaricides to the Papaya. *Hawaii.Agric.Exp.Sta.Tech.Bull.* 74: 5-63.

EcoReference No.: 25114
Chemical of Concern: DCF,ES,ADC,CBL,DCTP,DDVP,MVP,Naled,PPHD,DZ,DMT,PSM,TCF; Habitat: T; Effect Codes: PHY,GRO,CEL,MOR; Rejection Code: LITE EVAL CODED(Naled,DMT,PSM),OK TARGET(ADC),OK(CBL,DZ).

26. Short, R. D., Minor, J. L., Unger, T. M., Breeden, B., and Van Goethem, D. (1980). The Effect of Imidan Administered to Pregnant Rats. *EPA/600/1-80/008, U.S.Environmental Protection Agency, Washington, D.C.* 23 p. (NTIS/PB80-159627).

EcoReference No.: 96426
Chemical of Concern: PSM; Habitat: T; Effect Codes: PHY,REP,GRO,MOR,BEH; Rejection Code: LITE EVAL CODED(PSM).

27. Simonet, D. E., Knausenberger, W. I., Townsend, L. H. Jr., and Turner, E. C. Jr. (1978). A Biomonitoring Procedure Utilizing Negative Phototaxis of First Instar Aedes aegypti Larvae. *Arch.Environ.Contam.Toxicol.* 7: 339-347.

EcoReference No.: 60134
Chemical of Concern: CdS,CuS,CrO3,FNT,MOM,CBF,FNT,PSM; Habitat: A; Effect Codes: BEH,MOR; Rejection Code: LITE EVAL CODED(MOM,PSM),OK(CuS,CrO3,CBF).

28. Smith, C. R., Funke, B. R., and Schulz, J. T. (1978). Effects of Insecticides on Acetylene Reduction by Alfalfa, Red Clover and Sweetclover. *Soil Biol.Biochem.* 10: 463-466.

EcoReference No.: 64478
Chemical of Concern: CBF,ADC,PSM,CBL,CPY; Habitat: T; Effect Codes: GRO,BCM; Rejection Code: LITE EVAL CODED(PSM),OK(ADC,CBF,CBL,CPY).

29. Staples, R. E., Kellam, R. G., and Haseman, J. K. (1976). Developmental Toxicity in the Rat After Ingestion or Gavage of Organophosphate Pesticides (Dipterex, Imidan) During Pregnancy. *Environ.Health Perspect.* 13: 133-140.

EcoReference No.: 35457
Chemical of Concern: PSM; Habitat: T; Rejection Code: LITE EVAL CODED(PSM).

30. Varsik, P., Buranova, D., Kondas, M., Kucera, P., Goldenberg, Z., and Pokorna, V. (2005). Chronic Toxic Neuropathy After Organophosphorus Poisoning in Quails (Coturnix coturnix japponica). *Bratisl.Lek.Listy* 106: 293-296.

EcoReference No.: 95291
Chemical of Concern: PSM; Habitat: T; Effect Codes: PHY; Rejection Code: LITE EVAL CODED(PSM).

Acceptable for ECOTOX but not OPP

1. Abd-Elsalam, A. M., Minessy, F. A., Eldafrawi, M. E., Hammad, S. M., and Zeid, M. M. (1969). Effect of Different Insecticides on Fruit Quality of Two Varieties of Oranges. *Alex.J.Agric.Res.* 16: 143-158.

Chemical of Concern: PSM; Habitat: T; Rejection Code: EFFICACY (PSM).

2. Abdelsalam, E. B. (1999). Neurotoxic Potential of Six Organophosphorus Compounds in Adult Hens. *Vet.Hum.Toxicol.* 41: 290-292.

EcoReference No.: 83898
Chemical of Concern: DZ,CMPH,PPHD,DDVP,TCF,PSM; Habitat: T; Effect Codes: BCM,PHY; Rejection Code: NO ENDPOINT(ALL CHEMS).

3. Abrol, D. P. and Bhat, A. A. (1996). Effect of Spacing, Intercropping and Insecticides on the Management of Tomato Fruit Borer, Helicoverpa armigera (Hubner). *J.Insect Sci.* 9: 170-171.

Chemical of Concern: PSM; Habitat: T; Rejection Code: EFFICACY (PSM).

4. Abu, J. F. and Ellis, C. R. (1977). Toxicity of Five Insecticides to the Alfalfa Weevil, Hypera postica, and Its Parasites, Bathyplectes curculionis and Microctonus aethiopoides. *Environ.Entomol.* 6: 385-389.

Chemical of Concern: PSM; Habitat: T; Rejection Code: EFFICACY (PSM).

5. Ackermann, H., Seidler, H., Kagan, Y. S., and Voronina, V. M. (1976). Metabolic and Toxic Behavior of Phthalimide Derivatives. I. Fate of Imidan in the Fetus. *Arch.Toxikol.* 36: 127-137.

EcoReference No.: 94891
Chemical of Concern: PSM; Habitat: T; Effect Codes: ACC; Rejection Code: NO ENDPOINT,NO CONTROL(PSM).

6. Adkisson, P. L. and Nemec, S. J. (1967). Insecticides for Controlling the Bollworm, Tobacco Budworm and Boll Weevil. *Misc.Publ.No.MP-837, Agric.Exp.Stn., TX* 7 p.

Chemical of Concern: PSM; Habitat: T; Rejection Code: TARGET (PSM).

7. Adlerz, W. C. (1978). Pickleworm Control on Cantaloupe and Summer Squash. *In: Proc.Fla.State Hortic.Soc.* 90: 399-400.

Chemical of Concern: PSM; Habitat: T; Rejection Code: EFFICACY (PSM).

8. Ahrens, E. H., Davey, R. B., George, J. E., and Pemberton, J. R. (1995). Management of a Phosmet-Charged Dipping Vat and the Control of Boophilus annulatus. *Southwest.Entomol.* 20: 335-340.

Chemical of Concern: PSM; Habitat: T; Rejection Code: EFFICACY (PSM).

9. Ajami, A. M. (1975). Inhibitors of Ester Hydrolysis as Synergists for Biological Activity of Cecropia Juvenile Hormones. *J.Insect Physiol.* 21: 1017-1025.

Chemical of Concern: PSM; Habitat: T; Rejection Code: TARGET (PSM).

10. AliNiazee, M. T. and Stafford, E. M. (1973). Management of Grape Pests in Central California Vineyards. 1. Cultural and Chemical Control of Platynota stultana on Grapes. *J.Econ.Entomol.* 66: 154-157.

Chemical of Concern: PSM; Habitat: T; Rejection Code: EFFICACY (PSM).

11. Alston, D. G. (1992). Western Cherry Fruit Fly Control of Tart Cherry 1990 and 1991. *Insectic.Acaric.Tests* 17: 57.

Chemical of Concern: PSM; Habitat: T; Rejection Code: TARGET (PSM).

12. Anonymous (1982). Insecticidal Compositions. *Res.Disclosure* 219: 271-272.

Chemical of Concern: PSM; Habitat: T; Rejection Code: TARGET (PSM).

13. Ardo, J. (1974). K Otazke Akutnej Toxicity Niektorych Pesticidov. (Acute Toxicity of Some Pesticides). *Vodni Hospod.* 24: 222-224 (SLO).

EcoReference No.: 6102
Chemical of Concern: MLN,DDVP,TCF,PSM; Habitat: A; Rejection Code: NO FOREIGN,NO CONTROL(ALL CHEMS).

14. Arne, C. N., Becker, S. A., and Bailey, W. C. (1991). Alfalfa Weevil Control Missouri (Northern), 1989. *Insectic.Acaric.Tests* 16: 123 (1F).

EcoReference No.: 90636
Chemical of Concern: MLN,CBL,PMR,EFV,CYF,CYP,CBF,LCYT,PSM,TDC,CPY; Habitat: T; Effect Codes: POP; Rejection Code: OK TARGET(ALL CHEMS),OK(CBF),TARGET(PSM).

15. Asquith, D. (1970). Codling Moth, Read-Banded Leaf Roller, Apple Aphid, Europena Red Mite, and Two-Spotted Spider Mite Control on Apple Trees. *J.Econ.Entomol.* 63: 181-185.

Chemical of Concern: PSM; Habitat: T; Rejection Code: EFFICACY (PSM).

16. Atwood, S. T., Sheets, T. J., Sutton, T. B., and Leidy, R. B. (1987). Stability of Selected Pesticide Formulations and Combinations in Aqueous Media. *J.Agric.Food Chem.* 35: 169-172.

EcoReference No.: 90321
Chemical of Concern: AZ,MZB,Captan,PSM,CPY; Habitat: T; Effect Codes: ACC,REP,GRO; Rejection Code: NO FATE(PSM),TARGET(MZB,Captan),NO MIXTURE(AZ,CPY).

17. Avrahami, M. and White, D. A. (1978). Phosmet Residues in Milk of Cows After "Pour-on" and Spray Treatments. *N.Z.J.Exp.Agric.* 6: 119-122.

EcoReference No.: 35692
Chemical of Concern: PSM; Habitat: T; Effect Codes: ACC; Rejection Code: NO ENDPOINT,NO CONTROL(PSM).

18. Ayers, J. C. Jr. and Barden, J. A. (1975). Net Photosynthesis and Dark Respiration of Apple Leaves as Affected by Pesticides. *J.Amer.Soc.Hort.Sci.* 100: 24-28.

EcoReference No.: 43644
Chemical of Concern: PHSL,PRN,AZ,BMY,DLD,DOD,ES,FBM,PHSL,PPHD,THM,OML,MLN,Zineb,CBL,Folpet,DINO,PSM; Habitat: T; Effect Codes: BCM; Rejection Code: NO CONTROL,ENDPOINT(Folpet),OK(ALL CHEMS),NO COC(Maneb).

19. Aziz, S. A. (1973). Toxicity of Certain Insecticide Standards Against the Southern Armyworm. *J.Econ.Entomol.* 66: 68-70.

Chemical of Concern: PSM; Habitat: T; Rejection Code: TARGET (PSM).

20. Bailey, P. T. and O'Sullivan, D. F. (1978). Insecticides Against Larvae of the Cacao Webworm Pansepta teleturga Meyrick (Lepidoptera: Xyloryctidae). *Papua New Guinea Agric.J.* 29: 27-31.

Chemical of Concern: PSM; Habitat: T; Rejection Code: EFFICACY (PSM).

7. Final Report About the Percolation Study of Silicone Dc200 10 Cs Through Soil With Cover Letter Dated 04/20/94. *Epa/ots; doc #86940001398*.
Chem Codes: Chemical of Concern: PSM Rejection Code: FATE.

ABSTRACT: This study determined the ability of polydimethyl siloxane fluid to percolate through 3 types of soil, a Belgium loamy soil and two soils provided by the Agricultural Ministry of Speyer, Germany (Speyer 2.1 and Speyer 2.2). About 5 grams of test substance was mixed in a 5 cm soil depth. Soil and silicone were added to a 450 mm polypropylene column in alternate layers and the column stoppered to avoid loss of volatile compounds. After a 24 hour adsorption period, elution with 0.005 molar aqueous calcium chloride was begun. The elution consisted of 6 two hour periods per day and the total amount eluted was 196.5 ml per day. The eluat
ABSTRACT: e was collected daily, extracted with methylisobutylketone and silicone contents determined with atomic absorption. After the 15 day leaching period the wet soil was extracted with toluene and silicone content analyzed for using atomic absorption. At the same time volatile silicones were analyzed for using atomic absorption. Results indicated that 0.16 to 0.28 percent of silicone percolated through the Speyer 2.1 soil column, 0.2 percent percolated through the Speyer 2.2 soil column and 0.3 to 0.47 percent through the loamy soil column. Some test substance was lost by evaporation although this amount was less than in the leachates.
ABSTRACT: In loamy soil the test substance was found in only the first 15 cm as compared to the Speyer soils where it was found in 20 to 25 cm depths. Recovery from loamy soil did not exceed 85 percent but was essentially complete in the Speyer soils.

9. Guide to California Water Right Appropriations. *Govt reports announcements & index (gra&i), issue 18, 2005*.

Chem Codes: Chemical of Concern: PSM Rejection Code: NO TOX DATA.

ABSTRACT: The California Constitution says the state's water resources belong to all Californians. Any citizen may use water for beneficial purposes by possessing a water right. Some ri ghts come with ownership of land adjacent to streams, lakes, or ponds. Similarly, right to use water which percolates beneath the ground may be claimed by overlying landowners. Another kind of water right - an appropriative water right - may be established by obtaining a permit, or in the case of a small domestic use, a certificate of registration, which spells out the terms and conditions for taking and using water in California.

13. Re-Evaluation of Phosmet. *Govt reports announcements & index (gra&i), issue 05, 2005*.
Chem Codes: Chemical of Concern: PSM Rejection Code: REVIEW.

ABSTRACT: Proposed acceptability for continuing registration no. PACR2004-38.
ABSTRACT: French ed.: 104-07728/1.
ABSTRACT: Organophosphate active ingredients in pest control products have been subject to re-evaluation since 1999. As part of this initiative, this document summarizes the data & information reviewed regarding phosmet, a broad-spectrum organophosphate insecticide registered for use on a wide variety of crops as well as livestock. It includes information on the product's current registered uses; effects having relevance to human health, including those resulting from occupational & dietary exposure; environmental fate, impacts, & toxicology; and the value of phosmet in agricultural applications. The final sections include an outline of other issues considered in the assessment of phosmet; proposed regulatory actions, such as mitigation measures & use limitations; and additional data required from registrants of the product.

ABSTRACT: Introduction: Previous studies have shown that bronchos- copic examinations in patients with vibroacoustic disease (VAD) reveal the presence of small pink lesions (PL), bila- terally and near the spurs. The goal of this report is to des- cribe the histological features of the PL epithelium and its adjacent, apparently normal, epithelium. Methods: Volunteer VAD patients, with consented know- ledge and the approval of the Ethics Committee, received bronchoscopic examinations during which biopsies were removed from both the PL region and the adjacent, appa- rently normal, epithelium. Collected fragments were pro- cessed for histological analysis. Results: In spite of the visually vascular nature of the PL, biopsy procedure did not produce any hemorrhagic event. On the surface, cilia are histologically normal but are not very frequent, and constant stratification is seen in the epithelial cells. Deep within the epithelial cells, in the transition to the basal lamina, numerous thin small vessels were observed, and in the PL fragments, some of these small this vessels were ruptured. The more su- perficial epithelial cells showed a large reinforcement of cytoskeletal structures, as well as images of apopto- tic processes. In these cells, there is also a reinforce- ment of inter-cellular connections, namely a large num- ber of desmosomes. In ciliated cells, more that one axoneme surrounded by the same membrane was frequently observed. Degenerative changes of the basal bodies were also seen. Conclusions: The constant images epithelial statification and the accelerated rate of cellular turn-over, suggest the existence of an adaptation mechanism of the epithelium to prolonged situations of mechanical stress, i.e., LFN-expo- sure. If the mutagenic effect of LFN is taken into account (increased sister chromatid exchanges), then the abnormal frequency of squamous-cell carcinomas in VAD patients mi- ght not be so surprising. Key-words: Pink lesions, cilia, vessels, cytoskeleton, desmo- somes, squamous-cell carcinoma.

ABSTRACT: PESTAB. The embryotoxicity of phthalophos (phosmet) was studied in pregnant rats subjected to intragastric or peroral administration of oil-base solution of phthalophos at 0.3, 1.5 and 5 mg/kg from day 1 of gestation. On day 20 of gestation rats were sacrificed and the number and weight of embryos was determined. Phthalophos at 5 mg/kg had a marked teratogenic and embryotoxic effect. Peroral administration of phthalophos at 1.5 mg/kg had a mild embryotoxic effect (the frequency of stillborns was 10%, compared with 4% in controls). Phthalophos at 0.3 mg/kg had no teratogenic or embryotoxic effect.

ABSTRACT: PESTAB. Gas-chromatographic determination of phosmet residues in meat, milk, eggs, fish and water is described. Following extraction (with n-hexane from water, with acetone from all other materials) the extract is purified; phosmet is reextracted with n-hexane and determined on a gas chromatograph with electron capture detector, using a column with silanized methylsiloxane on Chromatone, and nitrogen as carrier gas. The column temperature is 230"C, the evaporator and detector temperature is 250"C. With a 70-cm column, the retention time is 1.5 min. Quantitative determination is done by peak height comparison against a reference. The sensitivity amounts to 0.15 ng/sample. The recovery rates are 80+-5% for milk, 85+-5% for meat and fish, 70+-8% for eggs, and 95+-5% for water.

ISSN: 0014-8962
Abstract: Pollen morphology of 39 species belonging to 23 genera of the tribes Arabideae, Euclidieae, Hesperideae, Lunarieae, Matthioleae and Sisymbrieae from Brassicaceae from Egypt were studied by using scanning electron microscope (SEM). The pollen grains were tricolpate. Their shape varies from prolate spheroidal, subprolate to prolate. Three pollen types can be distinguished based on the size of the lumina. The ornamentation varies between genera within the tribes and between species within the same genus. The ornamentation was found useful to distinguish among closely related genera such as Matthiola, Morettia and Diceratella and among species in the same genus such as Arabis, Morettia, Malcolmia and Neotorularia. Our results suggest that tribes Sisymbrieae, Matthioleae, Hesperideae and Arabideae are heterogeneous because all three types of ornamentation are found among the genera of these tribes. However, the tribes Euclidieae and Lunarieae are homogeneous because we found only one type of ornamentation among the genera.

Chem Codes: Chemical of Concern: PSM Rejection Code: NON-ENGLISH.

ABSTRACT: PESTAB. The effects of organophosphorus insecticides on pregnant albino rats were determined. Methylparathion, bromophos, and imidan (phosmet) ip were detectable from the placenta, liver, brain, muscle tissue, and fetuses of the rats. The PO isologue of methylparathion was detected in all embryonal tissue. When testing for bromophos and imidan, only traces of bromoxon, the PO isologue of bromophos, were recorded from fetal muscular tissue, while the imidan isologue was not detectable. Toxic symptoms were triggered during acute intoxication, which is in direct relation with PO isologue formation. During acute intoxication no direct relation existed between the applied dose of thionophosphoric acid compound and the inhibition of serum cholinesterase. Relations were established between the severity of intoxication and the occurrence of methyl-paraoxon as well as the inhibition of cholinesterase in muscle tissue, and in particular, muscle of the abdominal region.

Chem Codes: Chemical of Concern: PSM Rejection Code: NO SPECIES (DEAD), FATE.

ABSTRACT: PESTAB. The residue dynamics of phosalone, phthalophos (phosmet), rogor (dimethoate), anthio (formothion), carbophos (malathion) and gardona (tetrachlorvinphos) was studied in apples, tangerines and grapes after they were sprayed with 0.2% emulsions of these preparations. The residue half-life periods decreased in the order phosalone, phosphamide, gardona, phthalophos, carbophos and anthio, which largely corresponded to the rates of acid

hydrolysis of these pesticides. The rate of degradation was lower in the flesh than in the skin for phosalone and phthalophos, while the degradation of rate of anthio, phosphamide, and partly also of carbophos was higher in the flesh than in the skin.

Single lab. validation of the method was carried out for 28 compds. selected from 8 pesticide classes, in blank and fortified samples of fresh pear, cantaloupe, white potato, and cabbage. The method had to meet specific established validation criteria for regulatory purposes applicable to the lab. At each of the 2 fortification levels studied, 24 of the 28 pesticides gave recoveries of

more than 70% with a coeff. of variation of less than 10%. With respect to existing procedures, the method showed acceptable limits of detection (from 0.0019 to 0.14 mg/g depending on the pesticide and matrix) while minimizing environmental concerns, time, and labor. Chem Codes: Chemical of Concern: PSM Rejection Code: CHEM METHODS.

ABSTRACT: Nucleotide alkyl esters are pharmacologically important as potential (ant)agonists of purinoceptors and inhibitors of enzymes. Potato nucleotide pyrophosphatase (PNP) was compared with snake venom phosphodiesterase (SVP) as a catalyst to synthesize nucleotide alkyl esters. In methanol-water mixtures, the methanolysis/hydrolysis ratio of PNP, but not SVP, changed with pH and temperature, being optimal at high pH and low temperature. In a semi-preparative experiment, a crude PNP preparation produced 0.17 mM AMP-O-methyl ester (AMP-OMe) from 1 mM diadenosine 5',5"'-P1,P2-diphosphate (AppA) and 5M methanol, at pH 9 and 0 degrees C. Drawbacks to large-scale use are: low rates inherent to low temperatures, ATP unsuitability as a substrate for alcoholysis, and high cost of AppA. Advantages of PNP vs. SVP are cheapness, non-toxicity, and availability of the enzyme source.

27. Aiyuk, S., Forrez, I., Lieven De, K., Van Haandel, A., and Verstraete, W. (Anaerobic and Complementary Treatment of Domestic Sewage in Regions With Hot Climates--a Review. *Bioresour technol. 2006, nov; 97(17):2225-41. [Bioresource technology]: Bioresour Technol.*
Chem Codes: Chemical of Concern: PSM Rejection Code: BACTERIA, FATE.

ABSTRACT: This study presents a literature review on the treatment of domestic sewage in controlled environments having the anaerobic process and specifically the upflow anaerobic sludge blanket (UASB) concept as the core, under natural hot conditions. The UASB process application is however beset by the preponderance of suspended solids, and the paper looks at its optimization via pre- and post-treatments to curb the prevailing problems, in the light of possible discharge and re-use/recycling/resource recovery, leading to efficient environmental protection. Pre-treatment clarification could be done with ferric chloride/polyelectrolyte, so that phosphate precipitates during the process. The pre-treated liquid phase can be submitted to a high rate anaerobic process, using the simple and robust UASB technology. In a subsequent post-treatment step, ammonium can be removed by ion exchange using a zeolite column through which the wastewater percolates after leaving the anaerobic digester. The various stages can also eliminate a large fraction of the pathogens present in the raw wastewater, mainly through the pre-treatment sedimentation and the ion exchange filtration. The sludge produced in the precipitation stage can be stabilized in a conventional anaerobic digester. Integration of the different treatment steps

provides a sustainable technology to treat domestic sewage under hot climate conditions.

Chem Codes: Chemical of Concern: PSM Rejection Code: CHEM METHODS.

ABSTRACT: BIOSIS COPYRIGHT: BIOL ABS. A method was developed for determining 107 pesticides in agricultural products. Residues were extracted from samples with acetonitrile, and coextractives were removed with both ODS and PSA mini-column cleanup. Analysis was performed by gas chromatography with mass spectrometry. Positive analytes were confirmed on the basis of retention time and relative response ratio of two fragment ions. A limit of detection of 0.01 ppm was available for all compounds with two injections per sample for both scan and selected ion monitoring mode analyses. Recovery data were obtained by fortifying 3 matrices (brown rice, lemon, and spinach) at 0.1 ppm. Recoveries were more than 50% except for 6 pesticides, whose recoveries varied among the different matrices. The method demonstrated acceptable performance for screening analysis (including polar compounds). The method was applied to 157 samples. From 69 samples, 34 pesticides were detected at levels of more than 0.01 ppm. No sample was c

Citations: 20) Hajslova, J; J Chromatogr 1998, 800, 283 Proficiency test results from 5 countries involving 61 sep. interlab. tests for pesticide residues were examd. A total of 24 matrixes and 869 relative std. deviations of the mean (or median) pesticide residue concn. were statistically evaluated in relation to the Horwitz function (Horwitz, W.; 1998). The aim was to det. whether or not the concn.-dependent relationship described by Horwitz would hold for the much narrower range of chems. and concns. covered in routine pesticide residue anal. Although for fatty (animal-derived) matrixes the variability increased as the concn. decreased in line with the Horwitz equation, the between-labs. relative std. deviations for nonfatty matrixes (fruit, vegetables, and

grain) remained at 25% over the entire concn. range of 1 mg/kg to 10 mg/kg for the pesticides studied. Given these findings, the Horwitz equation remains valid for calcg. uncertainties involving pesticide residues in fatty matrixes. However, for pesticide residue analyses involving nonfatty matrixes, a const. relative std. deviation of 25% is more appropriate for calcg. uncertainties, particularly when a reported result is assessed against a regulatory limit. Citations: 40) Anon; EKeeper software for evaluation of the level of persistence of chemicals in environment, http://www.mis.tutkie.tut.ac.jp/ A data set of 420 pesticide persistence in the environment was collected as field half-life (HL) using several online databases. Due to the fuzziness of obsd. values, the compds. were grouped into three major categories: class 1 when a pesticide has HL ? 30 days; class 2, if 30 < HL ? 100 days; and class 3, if HL > 100 days. The Quant. Structure-Biodegrdn. Relationship (QSBR) anal. was worked out on the training set of 315 pesticides. Thirty one topol. substructural descriptors were used and the decision tree approach was employed for the modeling. Estn. results were as follows: for the train set, 5 compds. of two-unity (class 1/class 3) misclassification, 38 compds. of unity (class 1/class 2 and class 2/class 3) misclassification, and 272 compds. (86.3%) were correctly classified; for the test set, there were 3, 20, and 82 compds. (78.1%) resp. The computer expert system EKeeper was developed on the basis of the QSBR model. 32. Alvarez, B., Denicola, A., and Radi, R. (1995). Reaction Between Peroxynitrite and Hydrogen Peroxide: Formation of Oxygen and Slowing of Peroxynitrite Decomposition. *Chemical research in toxicology* 8: 859-864.
Chem Codes: Chemical of Concern: PSM Rejection Code: CHEM METHODS.

ABSTRACT: BIOSIS COPYRIGHT: BIOL ABS. Peroxynitrite, the reaction product of nitric oxide and superoxide, is a potent and versatile oxidant that can attack a wide range of targets. In this work, we studied the oxidation of hydrogen peroxide by peroxynitrite; which led to oxygen evolution. Oxygen yields increased at alkaline pH with an apparent pKalpha of 7.05 | 0.04. The maximum yields were 16% and 32% of added peroxynitrite at pH 5.9 and 7.4, respectively, assuming that two molecules of peroxynitrite are needed to produce one of oxygen. Hydroxyl radical scavengers (dimethyl sulfoxide, mannitol, ethanol, formate, and acetate) inhibited oxygen evolution to a similar extent to that predicted from their rate constants with hydroxyl radical. The apparent rate constant of peroxynitrite decomposition was zero-order in hydrogen peroxide at

acidic pH. At neutral and alkaline pH; the rate of peroxynitrite disappearance decreased in the presence of millimolar concentrations of hydrogen peroxide by up to 50%. The appa

<u>Chem Codes</u>: Chemical of Concern: PSM <u>Rejection Code</u>: SURVEY.

ABSTRACT: PESTAB. The results of pesticides residue analyses in feedstuff samples, performed in Hungary during the period 1974-1978, are presented. A total of 939 barley samples were examined for 23 active agents, including aluminum phosphide, diazinon, dichlorvos, lindane, DDT, MCPA and 2,4-D. The levels found exceeded the respective maximum residue levels (MRL) for aluminum phosphide in 1 of 18 samples and for dichlorvos in 3 of 9 samples. The levels were below the detection limit in 853 samples. A total of 2010 wheat samples were investigated for 37 active agents, including aldrin, alpha-BHC, aluminum phosphide, benomyl, diazinon, diquat, endosulfan, lindane and DDT. Levels exceeding the MRL were found in 296 samples. Levels were below the detection limit in 1344. The residues of 53 active agents, including actinit PK, aldrin, aluminum phosphide, dieldrin, phorate, phosphamidon, phosmet, lindane, DDT and 2,4-D were analyzed in 7666 corn samples. The residue levels exceeded the MRL in 1 case, and were below the detection limit in 500 cases. Residues of 30 active agents, including diquat dibromide, diuron, endosulfan, phencapton, lindane, monocrotophos and paraquat dibromide, were measured in 347 fresh alfalfa samples. The residue levels exceeded the MRL in 3 cases and were below the detection limit in 313 cases. Residue levels exceeding the MRL were found in 4 of 24 dry alfalfa samples, in 25 of 424 sunflower seed samples, and in 2 of 141 soybean samples.

Citations: 11) Ambrus, A; Pesticide Chemistry and Bioscience: Food and Environment Challenge 1999, 339 The uneven distribution of pesticide residues among the treated objects leads to an inevitable variability of pesticide residue levels measured in the samples, which may significantly contribute to the combined uncertainty of the anal. results. A total of 8844 unit-crop residue data derived from 57 lots and 19 field trials were evaluated to det. the characteristic features of residue distribution in unit crops and composite samples. The av. residue levels and the corresponding coeff. of variation (CV) values obtained for individual units taken from a given lot showed wide variation from lot to lot. There was no significant difference between the CVs of residue levels in sample sets of various unit crops or composite sample populations of different sizes taken from various crops. The CV values for levels of residues taken from individual lots followed normal distribution. Very good correlation was found between the CVs of the parent and sample populations. The exptl. obtained values were very close to those expected on the basis of the central limit theorem. The estd. typical relative std. uncertainties of sampling medium-size crops for pesticide residue anal. in the cases of sample sizes of 5, 10, and 25 were 37, 25, and 16%, resp. Three liq.-liq. extn. (LLE) procedures based on (i) partition of pesticides between acetonitrile (ACN) and oil soln. in n-hexane, (ii) partition of pesticides between satd. ACN with n-hexane and oil soln. in n-hexane satd. with ACN, and (iii) partition of pesticides between ACN and oil were tested for the optimization of the highest pesticide recoveries with the lowest oil residue in the final exts. Exptl. tests were preformed in order to study the efficiency of different clean up procedures with N-Alumina, Florisil, C18, and ENVI-Carb solid-phase extn. (SPE) cartridges for the compds. analyzed by GC-nitrogen phosphorus detection. A second step of clean up was also performed for the compds. analyzed by GC-electron capture detection (ECD), by using phenyl-bonded silica (Ph), diol-bonded silica (Diol), cyanopropyl-bonded silica (CN), and amino propyl-bonded silica (NH2) SPE cartridges. LLE of the oil soln. in hexane with ACN followed by an ENVI-Carb SPE clean up of the ext. gave the best results for all target compds. The ACN ext. was addnl. cleaned through a Diol-SPE cartridge for the detn. of pesticides analyzed mainly by GC-ECD. Pesticide recoveries form virgin olive oil spiked with 20, 100, and 500 mg/kg concns. of pesticides ranged from 70.9 to 107.4%. The proposed method featured good sensitivity, pesticide quantification limits were low enough, and the precision, expressed as relative std. deviation, ranged from 2.4 to 12.0%. The proposed method was applied successfully for the residue detn. of the selected pesticides in com. olive oil samples. [on SciFinder (R)] 0021-8561 pesticide/ olive/ oil/ extn/ GC

Agency of Environmental Protection about sales and use of pesticides in (NAEP) 2000
Citations: Warming, D; Technical Report 1997, 2
Citations: World Health Organization; Report on Environmental Health Criteria 1989, 91 The objective of the Danish pesticide monitoring program for fruit and vegetables was to check for compliance with the max. residue levels in foods and to monitor the residue levels to assess the pesticide exposure of the Danish population. Sampling plans were designed based on previous findings and on food consumption data. Approx. 60% of the samples were selected on the basis of pos. findings in samples from the previous 5 yr. The remaining samples reflected the pattern of food consumption in Denmark. In addn., a rolling program is maintained for commodities with a low consumption and no detected residues. Within each commodity, the sampling was random. Samples (n = 4150) of mainly fresh, conventionally grown fruit and vegetables were taken throughout the chain of suppliers including food-processing companies. Of the samples, 3% were frozen products and 2% were organically grown. Of the samples, 35% were of Danish origin, with 65% originating from other countries. Three accredited labs. performed analyses of the samples using capillary gas chromatog., liq. chromatog. and spectrophotometric methods. Results were registered online into a central database. Residues were found in 54% of the samples of fruit but only in 13% of the vegetables. Residues above the MRL were found in 4% of all samples of fruit and in 1% of vegetables. The Et acetate-method gave higher recoveries for polar pesticides and seems somewhat easier, quicker and cheaper in handling, but some co-extractives in the GC-ext. are obsd. In general, both methods gave acceptable and equiv. recoveries for the pesticides tested. [on SciFinder (R)] 0937-0633 pesticide/ extn/ detn/ food/ crop

Some of the samples (2.9%) contained residue levels above the Swedish max. residue limits (MRLs), and 6 of these samples exceeded the MRLs >10-fold. The percentage of samples exceeding the MRLs was smaller for domestic products than for imported products (0.3 and 4.0%, resp.). Apples, carrots, grapes, iceberg lettuce, pears, sweet peppers, potatoes, strawberries, and tomatoes also were checked for pesticide residues in the biased sampling program (anal. required before marketing because of previous residues above the MRL). Of 1056 samples analyzed, 186 (18%) exceeded the limits. No residues were found in the 356 samples of different kinds of juices or the 118 samples of canned or frozen fruits and vegetables analyzed. In the domestic samples, 33 pesticides were found at >=20% of the MRLs, and in imported samples, 62. [on SciFinder (R)] 0042-2657 pesticide/ fruit/ vegetable

A capillary gas chromatog. multiresidue method for the detn. of pesticide residues in fruits and vegetables is described. The method involves extn. with Me2CO, followed by partitioning of the residue to hexane/CH2Cl2. The ext. is then cleaned-up by gel permeation chromatog. on an SX-3 column and, finally, the pesticides are detd. by capillary gas chromatog. using different detectors (ECD, TSD, FPD, and FID). Addnl. clean-up is necessary for some foods and is performed on a Ag-loaded alumina column or a minicolumn of silica. Quant. recoveries (> 80%) were obtained with 126 of 134 tested pesticides and metabolites. The method has been used in Sweden since 1981 and >15,000 samples have been analyzed with it. Chem Codes: Chemical of Concern: PSM Rejection Code: CHEM METHODS.

Sedimentation ratios of oligomeric structures containing from two to five protomers in spatially equivalent positions are calculated on the basis of equations derived by Kirkwood. A range of

oblate and prolate protomers and a systematic set of assembly modes is considered for each type of oligomer. The results are presented graphically. Dimensions in three mutually perpendicular directions are also given for each structure considered, in a format which allows calculation in A of the dimensions of appropriate models for actual molecules. Together with the results for hexameric aggregates presented previously these data allow sedimentation velocity measurements with any oligomer, up to and including the hexamer, to be analysed readily and systematically in terms of quaternary structure. http://www.sciencedirect.com/science/article/B6TFB-44GPJ9H-C3/2/aee75e192ab74250693bc38622cf59fa

48. Andrews, P. R. and Jeffrey, P. D. (1976). The use of sedimentation coefficients to distinguish between models for protein oligomers. *Biophysical Chemistry* 4: 93-102.
Chem Codes: Chemical of Concern: PSM Rejection Code: CHEM METHODS.

The sedimentation coefficients of proteins are dependent on their sizes, shapes and densities and on the density and viscosity of the solvent. However, when the sedimentation coefficients of an oligomeric protein and its protomer are measured under the same experimental conditions, the ratio of the two coefficients depends only on the protomer shape and the mode of aggregation. This property, which we shall call the sedimentation ratio, therefore provides a way of distinguishing between models for oligomeric proteins. To allow examination of the behaviour of the sedimentation ratio, sedimentation coefficients are calculated for a comprehensive range of protomer shapes and modes of aggregation in hexameric systems using equations derived by Kirkwood. As illustrations of the method the resulting sedimentation ratios are compared with experimental values for insulin and arthropod hemocyanin, which eliminates many of the possible structures for these proteins. When experimental estimates of degree of hydration and molecular dimensions are also considered, all but a group of virtually identical structures are eliminated for the insulin hexamer and a single most likely structure remains for arthropod hemocyanin. The insulin structure is in good agreement with that determined by X-ray crystallography while the hemocyanin hexameric structure is a hexagonal prism formed by the cyclic aggregation of prolate ellipsoids of axial ratio about 2.5 : 1. http://www.sciencedirect.com/science/article/B6TFB-44GPHBN-2J/2/61e5d43478173ef0711209a5b966ad1f

Chem Codes: Chemical of Concern: PSM Rejection Code: FATE.

A 3-year study was conducted to determine whether differences existed in NO3-N concentrations under soils planted to conventional and no-till corn (Zea mays L.). Defined watersheds were instrumented with wells and suction lysimeters. Wells and lysimeters were also placed on the uphill side of the watersheds in a grassed control area. Groundwater and percolate were collected monthly and analyzed for NO3-N. The NO3-N in percolate collected from the grassed control was uniformly low, averaging 2 mgl-1. Few significant differences were detected between the two tillage systems, except in 1987. During the first 5 months of 1987, the percolate NO3-N concentration collected from a depth of 1.5 m was 15 and 30 mg l-1, for the no-till and conventional-till watersheds, respectively. The groundwater NO3-N concentration was consistently lower than the concentration in the percolate. The groundwater NO3-N concentration under the grassed control was generally low, averaging 2 mg l-1. For most of the months examined, the NO3-N concentration in groundwater from the watersheds was significantly greater than from the control area. The average groundwater NO3-N concentration of the two watersheds over the entire study was approximately 9 mg l-1. No significant difference was detected between the two watersheds except for 1984. In 1984, the groundwater NO3-N concentration from the conventional-till watershed was significantly greater than from the no-till watershed. These results indicate that the concentration of NO3-N under no-till cultivation is equal to or less than the NO3-N concentration under conventional-till cultivation.

53. Anina, I. A. (Possibility of Using Nucleic Acid Metabolic Indixes for Predicting Long-Term Consequences of the Effect of Some Pesticides. *Gig. Tr. Prof. Zabol. 3: 51-53* 1975..
Chem Codes: Chemical of Concern: PSM Rejection Code: NON-ENGLISH.

ABSTRACT: PESTAB. The effects of thiocarbamate pesticides (molinate, tillam, eptam), phthalophos, and DDT on the gonadal nucleic acid metabolism was examined in male rats in a study on the possible use of the metabolic changes as a prognostic factor for predicting the long-term consequences of the effects of these pesticides. The preparations were administered orally in a dose of 1/100 of LD50 during the last two months preceding sexual maturity. Molinate, phthalphos, and DDT caused a decrease in the nucleic acid level in the gonads, while tillam and eptam caused no significant changes. The disturbance in the nucleic acid metabolism in the gonads of rats treated with molinate, phthalophos, and DDT was due to their intensified decomposition and to inhibition of the nucleic acid synthesis. Similar changes were observed when the phthalophos dose was reduced to 1/300 LD50. Yalan, phthalophos, and DDT had been found to interfere with the reproductive function in earlier experiments, but tillam and eptam had no such effect. In view of this evidence, the recent findings indicate that the disturbances in the gonadal nucleic acid metabolism can be used for predicting long-term consequences of pesticides.

AGR (Agricultural use), BSU (Biological study, unclassified), SPN (Synthetic preparation), BIOL (Biological study), PREP (Preparation), USES (Uses) (prepn. of quinazolinones and pyridopyrimidinones for controlling invertebrate pests); 75-31-0 (Isopropylamine); 455-14-1 (4-Trifluoromethylaniline); 2402-77-9 (2,3-Dichloropyridine); 4389-45-1 (2-Amino-3-methylbenzoic acid); 5437-38-7 (3-Methyl-2-nitrobenzoic acid); 6388-47-2 (2-Amino-3-chlorobenzoic acid); 20154-03-4 (3-Trifluoromethylpyrazole) Role: RCT (Reactant), RACT (Reactant or reagent) (prepn. of quinazolinones and pyridopyrimidinones for controlling invertebrate pests); 20776-67-4P (2-Amino-3-methyl-5-chlorobenzoic acid); 23984-82-9P (2-Methyl-4-(trifluoromethyl)benzoic acid); 62639-14-9P (2-[(Methylthio)methyl]-4-(trifluoromethyl)benzenamine); 67169-22-6P (2-Methyl-4-(trifluoromethyl)benzenamine); 68289-10-1P (2-Amino-3-methyl-N-(1-methylethyl)benzamide); 362633-61-2P (2-Methyl-N-[2-methyl-6-[[(1-methylethyl)amino]carbonyl]phenyl]-4-(trifluoromethyl)benzamide); 362640-53-7P (3-Methyl-N-(1-methylethyl)-2-nitrobenzamide); 362640-55-9P; 362640-56-0P (2-Methyl-4-(trifluoromethyl)benzonitrile); 362640-63-9P (2-Methyl-4-(trifluoromethyl)benzoyl chloride); 438450-38-5P (3-Chloro-2-[3-(trifluoromethyl)-1H-pyrazol-1-yl]pyridine); 438450-39-6P; 438450-40-9P (6-Chloro-2-[1-(3-chloro-2-pyridinyl)-3-(trifluoromethyl)-1H-pyrazol-5-yl]-8-methyl-4H-3,1-benzoxazin-4-one); 438450-41-0P (N-[4-Chloro-2-methyl-6-[(methylamino)carbonyl]phenyl]-1-(3-chloro-2-pyridinyl)-3-(trifluoromethyl)-1H-pyrazole-5-carboxamide); 438450-42-1P (8-Chloro-2-[1-(3-chloro-2-pyridinyl)-3-(trifluoromethyl)-1H-pyrazol-5-yl]-4H-3,1-benzoxazin-4-one) Role: RCT (Reactant), SPN (Synthetic preparation), PREP (Preparation), RACT (Reactant or reagent) (prepn. of quinazolinones and pyridopyrimidinones for controlling invertebrate pests)
PCT Designated States: Designated States W: AE, AG, AL, AM, AT, AU, AZ, BA, BB, BG, BR, BY, BZ, CA, CH, CN, CO, CR, CU, CZ, DE, DK, DM, DZ, EC, EE, ES, FI, GB, GD, GE, GH, GM, HR, HU, ID, IL, IN, IS, JP, KE, KG, KP, KR, KZ, LC, LK, LR, LS, LT, LU, LV, MA, MD, MG, MK, MN, MW, MX, MZ, NO, NZ, PH, PL, PT, RO, RU, SD, SE, SG, SI, SK, SL, TJ, TM, TR, TT, TZ, UA, UG, US, UZ, VN, YU, ZA, ZW, AM, AZ, BY, KG, KZ, MD, RU, TJ, TM.
PCT Reg. Des. States: Designated States RW: AT, BE, CH, CY, DE, DK, ES, FI, FR, GB, GR, IE, IT, LU, MC, NL, PT, SE, TR, BF, BJ, CF, CG, CI, CM, GA, ML, MR, NE, SN, TD, TG.
Patent Application Country: Application: WO
Priority Application Country: US
Priority Application Number: 2000-254614
Priority Application Date: 20001211 The title compds. [I; B = O, S; J = (un)substituted Ph, naphthyl, 5-6 membered heteroarom. ring, etc.; K, together with the two contiguous liking carbon atoms = a fused Ph, or fused pyridinyl, each optionally substituted with 1-4 R4; R3 = G, alkyl, cycloalkyl, etc.; G = (un)substituted Ph, 5-6 membered heteroarom. ring, etc.; R4 = H, alkyl, haloalkyl, etc.; n = 1-4], useful for controlling invertebrate pests, were prepd. E.g. a multi-step synthesis of II which provided very good level of plant protection (20% or less feeding damage) in in test on diamondback moth (Plutella xylostella)/radish plant, was given. This invention also pertains to certain compds. I and compns. for controlling invertebrate pests comprising a biol. effective amt. of a compd. I and at least one addnl. component selected from the group consisting of surfactants, solid diluents and liq. diluents. 55. Anon (Fiscal Year 1984 Program Report: Maryland Water Resources Research Center. *Govt reports announcements & index (gra&i), issue 06, 1986*.
Chem Codes: Chemical of Concern: PSM Rejection Code: FATE.

ABSTRACT: TD3: Within the framework of the 1984 Program of the Maryland Water Resources Research Center, three projects were focused on questions of pollution of surface and ground water and one on acid rain. An information transfer project focused on the protection of ground water supplies. In a project to assess nitrogen and phosphorus losses via subsurface ground water flow from conventional and no-till corn watersheds, evidence was obtained that the leaching of nitrates into percolate or ground water is not enhanced by the use of no-till cultivation. No phosphate was found in percolate samples from either no-till or conventional cultivation treatments. A two-year study has been conducted to assess the accumulation of toxic metals in the

sediments of Maryland's Eastern Shore rivers. In a project to determine the impact on human health of contaminants present in sludge applied as soil amendment, ground and surface water have been analyzed for mutagenic compounds. Preliminary information on acidity in rainfal
KEYWORDS: Ground water
KEYWORDS: Water supply

56. Anon (Guidance for the Reregistration of Pesticide Products Containing Phosmet as the Active Ingredient. *Govt reports announcements & index (gra&i), issue 02, 1987*.
Chem Codes: Chemical of Concern: PSM Rejection Code: NO TOX DATA.

ABSTRACT: TD3: The document contains information regarding the reregistration of pesticide products containing the subject active ingredient. The document includes how to register under a registration standard, regulatory position and rationale, and summaries of data requirements and data gaps. Also included is a bibliography containing citations of all studies reviewed by EPA in arriving at the positions and conclusions contained in the standard.

A list of these insecticidal and acaricidal compds. is provided. Mixts. contg. alkoxylated amines may not only comprise one of the ingredients listed, but may comprise more than one of these active compds., forming for example, three-way or four-way mixts. Such combinations of alkoxylated amines with various active ingredients may have a broader spectrum of acaridical or insecticidal activity or a higher level of intrinsic acaricidal or insecticidal activity than the active ingredients alone, i.e., there may be a synergistic effect. Such synergism can be tested using std. insecticide or acaricide assays. [on SciFinder (R)] 0374-4353 alkoxylated/ amine/ insecticide/ acaricide/ synergism

ABSTRACT: TD3: The document contains up-to-date chemical information, including a summary of the Agency's regulatory position and rationale, on a specific pesticide or group of pesticides. A Fact Sheet is issued after one of the following actions has occurred. (1) Issuance or reissuance of a registration standard, (2) Issuance of each special review document, (3) Registration of a significantly changed use pattern, (4) Registration of a new chemical, or (5) An immediate need for information to resolve controversial issues relating to a specific chemical or use pattern.

63. Anon (Superfund Record of Decision (Epa Region 2): Syncon Resins Site, Kearny, New Jersey, September 1986. *Govt reports announcements & index (gra&i), issue 18, 1987.*
Chem Codes: Chemical of Concern: PSM Rejection Code: FATE.

ABSTRACT: TD3: The Syncon Resins site encompasses approximately 15 acres and is located in a heavily industrialized area of northern New Jersey. The Syncon Resin facility produced alkyd resin carriers for pigments, paints, and varnish products. In the production process excess xylene or toluene was separated from the wastewater and reused in subsequent reactions. The remaining wastewater was subsequently pumped to an unlined leaching pond (lagoon) to evaporate or percolate into the soil. The sampling performed during the remedial investigation indicated extensive onsite contamination in the soil, ground water, building dirt/dust, and stainless vessels and tanks. Four general classes of chemical contaminants were found onsite: organic compounds, pesticides, PCBs and metals. Final rept.

64. Anon (Superfund Record of Decision (Epa Region 5): Midco Ii, in. (First Remedial Action), June 1989. *Govt reports announcements & index (gra&i), issue 03, 1990*.

Chem Codes: Chemical of Concern: PSM Rejection Code: FATE.

ABSTRACT: TD3: The MIDCO II site is a seven-acre storage and disposal facility in Gary, Indiana. The surrounding area is predominantly used for industrial purposes, and includes 34 other potential hazardous waste sites. The underlying aquifer is highly susceptible to contamination from surface sources because of the high water table; however, in the vicinity of the site, the aquifer is used primarily for non-drinking water purposes. The same operator as at another Superfund site, MIDCO I, began waste operations, including drum storage at MIDCO II during the summer of 1976. Following a major fire at the MIDCO I site in January 1977, MIDCO transferred the operations from the MIDCO I site to the MIDCO II site. Operations included temporarily storing bulk liquid and drum wastes; neutralizing acids and caustics; and disposing of wastes by dumping wastes into onsite pits, which allowed wastes to percolate into the ground water. The resulting PCB-contaminated soil pile was removed and disposed of in an offsite hazard

65. Anon (Superfund Record of Decision (Epa Region 5): Wayne Reclamation and Recycling, Columbia City, Indiana (First Remedial Action), Final Report, March 30, 1990. *Govt reports announcements & index (gra&i), issue 24, 1991*.
Chem Codes: Chemical of Concern: PSM Rejection Code: FATE.

ABSTRACT: TD3: The 30-acre Wayne Waste Oil site is a former oil reclamation operation and municipal landfill in Columbia City, Indiana. The site overlies a contaminated unconsolidated surficial aquifer. From 1953 to 1970, part of the site was operated as a municipal landfill. From 1975 to 1982, waste oil reclamation activities, which included the storage and handling of hazardous wastes were conducted onsite. From 1979 to 1980, an estimated 250,000 gallons of hazardous waste were illegally dumped onsite and allowed to percolate into the soil. In addition the current landfill cap is not adequate to prevent exposure of buried landfill material. Site investigations by potentially responsible parties under a Consent Order from 1988 to 1989, characterized the location and extent of remaining contaminated media, and quantified the chemical contaminants at the site. The primary contaminants of concern affecting the soil, debris, and ground water are VOCs including benzene, PCE, TCE, toluene, and xylenes; other organi

ABSTRACT: PESTAB. Physical, chemical, and toxicological properties, physiological effects, and degradation of such anthelmintics as haloxon, coumaphos, trichlorfon, dichlorvos, and phthalophos are described. These pesticides are partly hydrolyzed and metabolized in the gastrointestinal tract of ruminants, and partial resorption takes place. The acute toxicity depends, among other things, on the particle size in the case of coumaphos and on the concentration in the case of trichlorfon. Phosphothionates are metabolized to phosphates by living organisms. The metabolites may be more toxic than the original compounds, as in the case of parathion which forms paraoxon, and coumaphos which metabolizes to coroxon. Trichlorfon is metabolized to the

equally toxic dichlorvos. Phosphates, carboxy esterases, and amidases inactivate organophoshorus compounds in the organism. Organophosphorus pesticides are eliminated rather rapidly from the system, but cause cholinesterase inhibition, parasympathetic excitation, muscular fasciculation, pareses, and depression of the respiratory center. Atropine and oximes are the best antidotes of organophosphorus pesticides.

Chem Codes: Chemical of Concern: PSM Rejection Code: CHEM METHODS.

ABSTRACT: BIOSIS COPYRIGHT: BIOL ABS. In 360 raw agricultural products imported in our country from countries non members of the European Union (245 of them were potatoes originating from Egypt) chemical analyses were performed for the determination of organophosphorus and organochlorine pesticide residues. In 14% of the samples, residues of organophosphorus and organochlorine pesticides were detected, while 1.7% of the samples contained residues above the Maximum Residue Limits (MRLs) which have been established from European Union or other International Organizations. The analytical methods used include gas-chromatography and GC-Mass spectrometry, and were assessed for efficiency, accuracy, repeatability as well as for the succeeded sensitivity of the above pesticides.

Chem Codes: Chemical of Concern: PSM Rejection Code: METHODS.

ABSTRACT: The polymerase chain reaction (PCR) has developed into one of the most promising methods for in vitro enzymatic amplification of DNA and has found widespread application in DNA cloning, sequencing and mutagenesis related studies. This innovative technique can selectively amplify a single target DNA molecule a billion-fold in a span of a few hours. Amplification of specific DNA sequences by PCR is useful in identification of sex, novel genes, pathogens and diseases. PCR has facilitated the establishment of evolutionary relationships among species and in revealing structural intricacies of single cells. In this article we review some of the major advances and applications of PCR, especially, its role in embryo sexing.

Chem Codes: Chemical of Concern: PSM Rejection Code: CHEM METHODS.

The vacuum distillation method of extracting soil water for stable isotope analysis was tested for three different types of soil characterized by high water content: (1) pure sand, (2) cambisol with high organic matter content, developed on calcareous sandstone under temperate climatic conditions (Austria), and (3) tropical latosol poor in organic matter, developed on sandy clay sediment (Brazil). The method yields accurate and reproducible results for sand, provided that more than 98% of the original soil water is extracted. The time required for complete extraction is a function of sample size and the applied extraction temperature. Column experiments with the clayey soils revealed existence of a weakly bound, easily exchangeable pool of water which is isotopically different from the mobile water. The experiments showed that the extracted soil water is depleted in both deuterium and oxygen-18 by 5-10% and 0.3-0.5%, respectively, when compared with the percolate (mobile water). This depletion depends strongly on the soil type. The reproducibility for replicate extractions of soil water from clayey soils is around +/-3% and 0.3% for [delta]D and [delta] 18O, respectively. http://www.sciencedirect.com/science/article/B6V6C-3Y6HJFJ-V/2/fe136455ccad576be1970deae2f46e87

Index Terms: Blood; Milk (analysis, detn. of toxaphene); Fats (toxaphene detn. in); Alfalfa (toxaphene detn. in hay from, calcns. in)
CAS Registry Numbers: 298-03-3 (Derived from data in the 7th Collective Formula Index (1962-1966); 732-11-6 (Phosphorodithioic acid, O,O-dimethyl ester S-ester with N-(mercaptomethyl)phthalimide) (chromatography of); 8001-35-2 (Toxaphene) (detn. of, in alfalfa hay, blood, fats and milk) The samples were extd. according to Crosby and Archer (CA 64, 20549b) except that benzene replaced pentane, and gave higher recoveries. The column was 9 ft. * 1/8 in., packed with 60-80-mesh, HMDS-treated Chromosorb W coated with 5% Dow 710 silicone oil and 5% SE gum rubber. The first ft. of the column was packed with 20-30-mesh CaC2 to remove traces of H2O and alc.; N was the carrier gas, and the flow rate was 40-60 ml./min. The column, detector, and injector temps. were 200, 190, and 250 Deg, resp. An electron-capture detector was used. The reproducible single peak obtained could not be confused with those of the DDT group. Recoveries from samples fortified with 0.1 and 0.5 ppm. were 74-95%. Nanogram quantities could be detected reproducibly. [on SciFinder (R)] 0007-4861

75. Arnt, J., S&Aacute, Nchez, C., Lenz, S. M., Madsen, U., and Krogsgaard-Larsen, P. (Differentiation of in Vivo Effects of Ampa and Nmda Receptor Ligands Using Drug Discrimination Methods and Convulsant/Anticonvulsant Activity. *Eur j pharmacol. 1995, oct 24; 285(3):289-97. [European journal of pharmacology]: Eur J Pharmacol*.
Chem Codes: Chemical of Concern: PSM Rejection Code: HUMAN HEALTH.

ABSTRACT: The discriminative stimulus properties of the AMPA ((RS)-2-amino-3-(3-hydroxy-5-methylisoxazol-4-yl)propionic acid) receptor agonist ATPA ((RS)-2-amino-3-(3-hydroxy-5-tert-butylisoxazol-4-yl)propionic acid) and NMDA (N-methyl-D-aspartic acid) in rats have been characterized. It is suggested that the cues are mediated by separate mechanisms in the central nervous system. The ATPA cue is not mimicked by NMDA or an NMDA receptor agonist, and is inhibited by the AMPA receptor antagonist (R)-APPA ((R)-2-amino-3-(3-hydroxy-5-phenylisoxazol-4-yl)propionic acid) but not the AMPA receptor antagonist ATOA ((RS)-2-amino-3-(3-carboxymethoxy-5-tert-butylisoxazol-4-yl)propio nic acid) or the NMDA receptor antagonist CPP ((RS)-3-(2-carboxypiperazin-4-yl)propyl)phosphonic acid). The ATPA cue is not mimicked by AMPA which is believed not to penetrate the blood-brain barrier. In contrast, ATPA does not generalize to the NMDA cue, which is mimicked by some NMDA receptor agonists (tetrazol-5-yl-glycine and AMAA ((RS)-2-amino-2-(3-hydroxy-5-methylisoxazol-4-yl)acetic acid)) and is inhibited by the NMDA receptor antagonist CPP. Highly potent convulsant activity was demonstrated in mice with all AMPA and NMDA receptor agonists after intracerebroventricular (i.c.v.) injection, whereas weaker or no effects were found after subcutaneous (s.c.) or intravenous injection. Only (RS)-tetrazol-5-yl-glycine had a potent effect after s.c. administration. I.c.v. ATOA and CPP inhibited convulsions induced by i.c.v. injection of AMPA or NMDA, while (R)-APPA was ineffective. These results indicate that there are differences in the structure-activity relations in the drug discrimination and convulsant/anticonvulsant models, even when effects after i.c.v. and s.c. injection are taken into consideration. The convulsion models are rapid tests which can give an indication of central nervous system penetration, but are less pharmacologically specific with respect to differentiation between AMPA and NMDA ligands where cue models demonstrate clear differences in effects of ligands with selectivity for receptor subtypes.

76. Asami, Koji and Yonezawa, Takeshi (1995). Dielectric behavior of non-spherical cells in culture. *Biochimica et Biophysica Acta (BBA) - General Subjects* 1245: 317-324.
Chem Codes: Chemical of Concern: PSM Rejection Code: CHEM METHODS.

In order to study dielectric behavior of non-spherical cells growing in suspension culture, a dielectric theory has been developed based on the shell-ellipsoid model that is a conducting ellipsoid covered with a thin insulating shell. The theory predicts three dielectric relaxations for a suspension of ellipsoidal cells with three different semiaxes. For prolate spheroidal cells with two different semiaxes that show two dielectric relaxations the effect of the axial ratio on the dielectric relaxations was examined in detail. The low-frequency relaxation attributed to the component along the major axis strongly depends on the axial ratio, while the high-frequency relaxation due to the component along the minor axis is rather insensitive to the axial ratio. The theory is also applicable to simulation of dielectric behavior of yeast cells in synchronized and asynchronized culture by assuming that budding yeast cells are prolate spheroids. Dielectric relaxation/ Permittivity/ Interfacial polarization/ Non-spherical cell/ Synchronized culture/ Growth curve

77. Asay, M. J. and Boyd, S. K. (Characterization of the Binding of [3h]Cgp54626 to Gabab Receptors in the Male Bullfrog (Rana Catesbeiana). *Brain res. 2006, jun 13; 1094(1):76-85. [Brain research]: Brain Res*.
Chem Codes: Chemical of Concern: PSM Rejection Code: IN VITRO.

ABSTRACT: Gamma-aminobutyric acid (GABA) is the main inhibitory neurotransmitter in the vertebrate brain. GABA activates both ionotropic (GABA(A)) and metabotropic (GABA(B)) receptors in mammals. Whether non-mammalian vertebrates possess receptors with similar characteristics is not well understood. We used a mammalian GABA(B)-specific antagonist to determine the pharmacology of putative receptors in the brain of an anuran amphibian, the male bullfrog (Rana catesbeiana). Receptor binding assays with the antagonist [(3)H]CGP54626 revealed a single class of high affinity binding sites (with a K(D) of 2.97 nM and a B(max) of 2619 fmol/mg protein). Binding was time- and temperature-dependent, saturable and specific. Specific binding of [(3)H]CGP54626 was inhibited by several mammalian GABA(B) receptor

agonists and antagonists. The rank order potency of agonists was: GABA = SKF97541 > (R)-Baclofen > 3-APPA. The rank order for antagonists was: CGP54626 = CGP55845 > CGP52432 > CGP35348. The GABA(A) receptor ligands muscimol and SR95531 had very low affinity for [(3)H]CGP54626 binding sites, while bicuculline compounds had no affinity. Binding of GABA was positively modulated by CGP7930. Taurine did not allosterically modulate GABA binding but did inhibit [(3)H]CGP54626 binding in a linear fashion. Bullfrog brain thus possesses binding sites with significant similarity to mammalian GABA(B) receptors. These receptors differ from mammalian receptors, however, in dissociation kinetics, ligand specificity and allosteric modulation.

78. Aschmann, S. G., Mcintosh, M. S., Angle, J. S., and Hill, R. L. (1992). Nitrogen Movement Under a Hardwood Forest Amended With Liquid Wastewater Sludge. *Agric ecosyst environ* 38: 249-263.
Chem Codes: Chemical of Concern: PSM Rejection Code: FATE.

ABSTRACT: BIOSIS COPYRIGHT: BIOL ABS. Owing to the limited quantity of agricultural land available for sludge disposal near urban centers, forests are being considered as potential land application sites. A major environmental concern regarding forest sludge application is the potential for nitrate leaching and subsequent groundwater contamination. This study was conducted to determine the effect of different sludge application rates on soil nitrogen (N) movement in a mature, mixed hardwood forest in Maryland (USA). Liquid municipal sewage sludge was applied to a forest at dry rate equivalents of 0, 3, 6, and 12 Mg ha-1 and loading rates of 0, 200, 400, or 800 kg total N ha- (one time application). Soil percolate samples were collected from November 1986 to June 1988 using suction lysimeters placed at 80 cm soil depth and analyzed for NO3-N. Soil was also sampled to a depth of 180 cm and analyzed for NO3-N each spring and fall from 1986 to 1988. One year after application, NO3-N concentrations in the soil pe

79. Ashokkumar, N., Pari, L., and Rao, C. H. A. (Effect of N-Benzoyl-D-Phenylalanine and Metformin on Insulin Receptors in Neonatal Streptozotocin-Induced Diabetic Rats: Studies on Insulin Binding to Erythrocytes. *Arch physiol biochem. 2006, jul; 112(3):174-81. [Archives of physiology and biochemistry]: Arch Physiol Biochem.*
<u>Chem Codes</u>: Chemical of Concern: PSM <u>Rejection Code</u>: HUMAN HEALTH.

ABSTRACT: In the present study, we focused on the insulin-receptor binding in circulating erythrocytes of N-benzoyl-D-phenylalanine (NBDP) and metformin in neonatal streptozotocin (nSTZ)-induced male Wistar rats. We measured blood levels of glucose and plasma insulin and the binding of insulin to cell-membrane ER receptors in NBDP and metformin-treated diabetic rats. The mean specific binding of insulin to ER was significantly lower in diabetic control rats (DC) (53.0 +/- 3.1%) than in NBDP (62.0 +/- 3.1%), metformin (66.0 +/- 3.3%) and NBDP and metformin combination-treated (72.0 +/- 4.2%) diabetic rats, resulting in a significant decrease in plasma insulin. Scatchard plot analysis demonstrated that the decrease in insulin binding was accounted for by a lower number of insulin receptor sites per cell in DC rats when compared with NBDP and metformin-treated rats. High-affinity (Kd1), low-affinity (Kd2), and kinetic analysis revealed an increase in the average receptor affinity in ER from NBDP and metformin-treated diabetic rats having NBDP 2.0 +/- 0.10 x 10(-10) M(-1) (Kd1); 12.0 +/- 0.85 x 10(-8) M(-1) (Kd2), Metformin 2.1 +/- 0.15 x 10(-10) M(-1) (Kd1); 15.0 +/- 0.80 x 10(-8) M(-1) (Kd2), NBDP and metformin 2.7 +/- 0.10 x 10(-10) M(-1) (Kd1); 20.0 +/- 1.2 x 10(-8) M(-1) (Kd2) compared with 0.9 +/- 0.06 x 10(-10) M(-1) (Kd1); 6.0 +/- 0.30 x 10(-8) M(-1) (Kd2) in DC rats. The results suggest an acute alteration in the number of insulin receptors on ER membranes in nSTZ induced diabetic control rats. Treatment with NBDP along with metformin significantly improved specific insulin binding, with receptor number and affinity binding reaching almost normal non-diabetic levels. The data presented here show that NBDP along with metformin increase total ER membrane insulin binding sites with a concomitant significant increase in plasma insulin.

80. Atabayev, S. H. T. and Iskandarov, T. I. (Theoretical and Practical Aspects of the Hygiene of the Use of Pesticides in a Hot Climate. *Med. Zh. Uzb.8: 16-23; 1973*.
Chem Codes: Chemical of Concern: PSM Rejection Code: HUMAN HEALTH.

ABSTRACT: PESTAB Studies on the theoretical and practical problems of the use of pesticides under a hot climate are reviewed. Pesticides accumulated more readily in soils with high organic matter content than in those with low organic content and were more easily accessible for plants from the latter type soils. Many pesticides like dimethoate and phthalophos cause persistent reduction in the vitamin C level in lemon and tomato even after the pesticides are no longer detectable. A study of the combined effects of high temperature (35 C) and anthio formothion, butyphos DEF, methylmercaptophos, BHC, and lindane in experimental animals revealed acute oral LD50 values of 122, 136, 76, 632, and 305 mg/kg, under normal temperature conditions, against 85, 80, 54, 370, and 215 mg/kg at high temperature. The changes in the electrolyte balance, blood picture, and blood cholinesterase activity were more pronounced under high-temperature conditions than under normal conditions in chronic poisoning tests. Reduced cholinesterase activity, increased sodium and potassium levels, and reduced choline level in the blood were determined in farm workers exposed to pesticides at high temperature. An extensive survey of rural populations in areas with massive use of pesticides revealed changes in the morbidity due to ischemic heart disease, respiratory troubles, malignant neoplasia, stillbirth and abortion, changes in the blood protein composition, and nearly constant presence of antibodies to organophosphorus and organochlorine pesticides in the blood.

81. Atlung, T., Nielsen, A., and Hansen, F. G. (Isolation, Characterization, and Nucleotide Sequence of Appy, a Regulatory Gene for Growth-Phase-Dependent Gene Expression in Escherichia Coli. *J bacteriol. 1989, mar; 171(3):1683-91. [Journal of bacteriology]: J Bacteriol.*
Chem Codes: Chemical of Concern: PSM Rejection Code: BACTERIA.

ABSTRACT: A plasmid carrying a regulator gene, designated appY, was found in the screening of an Escherichia coli gene library for clones overproducing AppA, an acid phosphatase which is induced as a culture approaches the stationary phase. In cells containing multicopy plasmids carrying the appY gene, the expression of the chromosomal appY gene was stimulated 10- to 40-fold in the stationary phase and more than 100-fold during exponential growth. The appA plasmid also changed the rate of synthesis of more than 30 other proteins in a growth-phase-dependent way. The appY gene was mapped to 13 min on the E. coli genetic map. The position of the appY gene on the 4.9-kilobase HindIII fragment of the original clone was located by Tn5 mutagenesis and deletion analysis, and the nucleotide sequence of a 1.9-kilobase region containing the gene was determined. The appY gene product was identified as a weakly expressed 243-amino-acid polypeptide which contains a stretch of 20 amino acids showing very good similarity to the conserved DNA-binding domain of repressors and transcriptional activators.

Citations: Pietschmann, M; Lebensmittelchemie 2000, 54, 102 A multi-residue method employing an extn. step with Et acetate followed by clean-up using an Isolute silica column and detn. using gas chromatog. with nitrogen-phosphorus and electron capture detection was validated for a wide range of pesticide residues in white and red wine. Recoveries between 70 and 110% and relative std. deviations below 20% were obtained for nearly all target analytes using matrix-matched stds. Limits of detection based on 3 times the signal-to-noise ratio were in the range 0.002-0.01 mg/L for most compds. The chromatograms were generally free of interference peaks resulting from co-extractives, although a few were noted for red wine with nitrogen-phosphorus detection. Ninety-two wine samples collected in Greece and Yugoslavia during 2 consecutive years were screened for residues of 84 pesticides, 71% of which were registered for use on vines in one or both countries. A total of 20% of the samples were obtained from field trials, and of these, one Greek wine contained iprodione 0.3 mg/L and 6 Yugoslavian wines, for which vinclozolin had been added to the must as part of a different study, contained residues of this pesticide. No residues were detected in any of the other samples. [on SciFinder (R)] 0265-203X pesticide/ residue/ detn/ wine/ GC

Citations: Wurpel, J; Neurotoxicology 1993, 14, 429 Speculation about potential neurotoxicity due to chronic exposure to low doses of organophosphate (OP) pesticides is not yet supported by exptl. evidence. The objective of this work was to use a cell culture model of chronic OP exposure to det. if such exposure can alter the sensitivity of nerve cells to subsequent acute exposure to OPs or other compds. NB2a neuroblastoma cells were grown in the presence of 25 mM diazinon for 8 wk. The OP was then withdrawn and the cells were induced to differentiate in the presence of various other pesticides or herbicides, including OPs and OP-contg. formulations. The resulting outgrowth of neurite-like structures was measured by light microscopy and quant. image anal. and the IC50 for each OP or formulation was calcd. The IC50 values in diazinon pre-exposed cells were compared with the equiv. values in cells not pre-exposed to diazinon. The IC50 for inhibition of neurite outgrowth by acute application of diazinon, pyrethrum, glyphosate, or a com. formulation of glyphosate was decreased by between 20 and 90% after pretreatment with diazinon. In contrast, the IC50 for pirimiphos Me was unaffected and those for phosmet or chlorpyrifos were increased by between 1.5- and 3-fold, resp. Treatment of cells with chlorpyrifos or with a second glyphosate-contg. formulation led to the formation of abnormal neurite-like structures in diazinon-pre-exposed cells. The data support the view that chronic exposure to an OP may reduce the threshold for toxicity of some, but by no means all, environmental agents. Abstract: Morphological, palynological, and karyological features of Ebenus longipes Boiss. & Bal. and E. argentea Siehe ex Bornm. have been examined in detail. Morphologically, stems, shape of leaves and pair of leaflets, bracts, calyx, flowers, and fruit structure are examined and discussed. Pollen grains of both species are radially symmetrical, isopolar, tricolpate, prolate, and ornamentations are microreticulate. Their exine structures are the same. Both species are diploid with the chromosome number of 14. All chromosomes are metacentric. One pair of chromosomes with a satellite is present in both species. Based on these results, E. argentea is reduced as synonym of E. longpipes.

(Evaluation of Toxic and Genotoxic Potential of Stabilized Industrial Waste and Contaminated Soils. *Waste manag. 2002; 22(2):241-7. [Waste management (new york, n.y.)]: Waste Manag*.
Chem Codes: Chemical of Concern: PSM Rejection Code: MIXTURE.

ABSTRACT: Artificial aqueous samples (eluates, percolates, immersion waters) were obtained from contaminated soils and stabilized industrial wastes. The toxicity and genotoxicity of these aqueous fractions have been evaluated in vivo in the aquatic larvae of the amphibian Xenopus

laevis. Four biotests have been applied: a test of subchronic toxicity and three biomakers: (1) measurement of the activity of ethoxyresorufine-o-dealkylase in the liver, (2) detection of DNA adducts in the liver and the blood, and (3) measurement of the rate of micronuclei in the erythrocytes. Biological datas were completed through a chemical analysis. The main conclusions of this study are: The importance of integrating different toxicity criterias into a biological battery (phenotypic and genotypic criterias). Some aqueous extracts did not seem to be very toxic, whereas their genotoxic effects were rather significant [e.g. the stabilized Municipal Solid Waste (MSW) ashes]. The importance of coupling together chemical and biological approaches to refine the impact. Actually, some eluates (lixiviation or percolation) coming from polluted soils appeared to be very poorly loaded with pollutants, whereas the toxic and genotoxic impact of these complex matrices were rather noticeable. In addition, when applying the leaching standardized procedure, the hazardous potential of the two analysed soils may be underestimated if the results on percolates and on eluates have been compared. This study highligths the importance of coupling the tools of characterization and preparation of samples to be analysed according to the objectives to be reached.

Chem Codes: Chemical of Concern: PSM Rejection Code: MODELING.

Knowledge-based potentials can be used to decide whether an amino acid sequence is likely to fold into a prescribed native protein structure. We use this idea to survey the sequence-structure relations in protein space. In particular, we test the following two propositions which were found to be important for efficient evolution: the sequences folding into a particular native fold form extensive neutral networks that percolate through sequence space. The neutral networks of any two native folds approach each other to within a few point mutations. Computer simulations using two very different potential functions, M. Sippl's PROSA pair potential and a neural network based potential, are used to verify these claims.

The type of sorbent, sorbent mass, flow rate in the extn. process, sample concn. of the different compds., sample vol., pH, and ionic strength were evaluated. Special emphasis was placed on the evapn. step of eluates prior to GC detns. and on prefiltration of sample waters. Pesticide recovery was linear over a wide range of concns. for most of compds. under study. Under general extn. conditions losses can be expected for amitraz, pro-metryn, prometon, dimethoate, penconazole, and propiconazole. At 100 ng/L, enhanced responses were produced for mevinphos, simazine, malathion, triadimefon, methidathion, and phosmet, which were attributed to matrix effects. At basic pH, recovery of prometon, prometryn, and penconazole were improved. Low flow rates and high ionic strength enhanced the recovery of prometon and prometryn. For phosmet, the influence of sample vol. was established. Likewise, the influence of sorbent quantity was established for phosmet and dimethoate. Losses during the evapn. step were obsd. for mevinphos, dimethoate (> 50%), penconazole, propiconazole, and prometon (30%). Prefiltration of sample waters did not cause significant variations in the whole process of extn. Impurities arising from the sorbent materials were not detected. 91. Bailey, T. L., Hudson, R. S., Powe, T. A., Riddell, M. G., Wolfe, D. F., and Carson, R. L. (1998). Caliper and ultrasonographic measurements of bovine testicles and a mathematical formula for determining testicular volume and weight in vivo. *Theriogenology* 49: 581-594.
Chem Codes: Chemical of Concern: PSM Rejection Code: MODELING.

This study quantified the relationship between calibrated caliper and ultrasonographic derived measurements of bovine testicles in vivo with actual testicular length, width, volume and weight. The prolate spheroid formula was tested to accurately predict testicular volume and a modification to predict weight. Ten bulls were employed to derive caliper and ultrasound testicle (n = 20) length and width measurements in vivo. Caliper length measurements were more reliable than ultrasound derived lengths, with correlations of $r2= 0.8023$; $P < 0.05$ and $r2= 0.5111$; $P < .05$, respectively. Width for both the calipers and ultrasound measurements when compared to actual width measurements were $r2= 0.7313$; $P < 0.05$ and $r2= 0.8310$; $P < 0.05$, respectively. The prolate spheroid formula is reliable in determining testicle (n = 116) volume ($r2= 0.8928$; $P < 0.05$). Testicular volume and weight are highly correlated ($r2= 0.9776$; $P < 0.05$); therefore, a modification of the prolate spheroid formula was used to predict weight ($r2= 0.9084$; $P < 0.05$) against the actual weight. Caliper-derived length and width measurements used in the prediction of volume and weight had correlation coefficients against actual volume and weight of r2= 0.5497; P < 0.05 and r2= 0.6340; P < 0.05, respectively. Ultrasound in vivo measurements for prediction of testicular volume and testicular weight had a correlation of r2= 0.3276; P < 0.05 and r2= 0.6249; P <0.05, respectively. A testicular (n = 116) length to width ratio of 1.8:1 (SEM = 0.01) was determined for both slaughterhouse and castrated animals. Caliper measurements are reliable, inexpensive and much simpler to obtain than ultrasound determinations for in vivo testicle length, width, volume and weight. The two-dimensional measurement of length and width would be a more accurate predictor of testicle volume and weight than the onedimensional measurement of scrotal circumference (SC), especially in bulls with variation in testicular shape. bovine/ testicle/ volume/ weight http://www.sciencedirect.com/science/article/B6TCM-3SJMWSS-8/2/5754fbca9848f6c8acb999d60b82d9ce

Thirty-eight pesticides representing several classes of compds. were evaluated for their potential to bind to P-gp, as measured by the inhibition of efflux of the P-gp substrate doxorubicin. Carbamate and pyrethroid insecticides exhibited little interaction with P-gp, while many of the organophosphorus and organochlorine pesticides significantly inhibited the efflux of doxorubicin. Pesticides that significantly inhibited the efflux of doxorubicin were then assessed for P-gp-mediated efflux. One pesticide, endosulfan, exhibited slight though significant transport mediated by P-gp. Competition expts. performed with the P-glycoprotein ligand [3H]azidopine demonstrated that the P-gp inhibitory pesticides bound to P-gp. Both lipophilicity and mol. mass were major phys./chem. determinants in dictating pesticide binding to P-gp, with optimum binding occurring with compds. having a log Kow value of 3.6-4.5 and a mol. wt. of 391-490 Da. The transport substrate endosulfan possessed optimal binding characteristics. These results demonstrated that many pesticides are capable of binding to P-gp; however, binding does not infer transport. [on SciFinder (R)] 0041-008X pesticide/ interaction/ P/ glycoprotein

Citations: 35) Hontela, A; Rev Toxicol in press The multixenobiotic resistance phenotype is characterized by the reduced accumulation of xenobiotics by cells or organisms due to increased efflux of the compds. by P-glycoprotein (P-gp) or related transporters. An extensive xenobiotic database, consisting primarily of pesticides, was utilized in this study to identify mol. characteristics that render a xenobiotic susceptible to transport by or inhibition of P-gp. Transport substrates were differentiated by several mol. size/shape parameters, lipophilicity, and hydrogen bonding potential. Electrostatic features differentiated inhibitory ligands from compds. not categorized as transport substrates and that did not interact with P-gp. A two-tiered system was developed using the derived structure-activity relationships to identify P-gp transport substrates and inhibitory ligands. Prediction accuracy of the approach was 82%. The authors then validated the system using six addnl. pesticides of which two were predicted to be P-gp inhibitors and four were predicted to be noninteractors, based upon the structure-activity analyses. Exptl. detns. using cells transfected with the human MDR1 gene demonstrated that five of the six pesticides were properly categorized by the structure-activity analyses (83% accuracy). Finally, structure-activity analyses revealed that among P-gp inhibitors, relative inhibitory potency can be predicted based upon the surface area or vol. of the compd. These results demonstrate that P-gp transport substrates and inhibitory ligands can be distinguished using mol. characteristics. Mol. characteristics of transport substrates suggest that P-gp may function in the elimination of hydroxylated metabolites of xenobiotics. Samples are previously extd. with an acetonitrile/n-hexane mixt. and cleaned up by gel permeation chromatog. Electron ionization and chem. ionization allow pesticides and PAHs to be detd. in a single anal. The precision obtained was quite satisfactory (relative std. deviations ranged from 3 to 7.8%), and so were recoveries (84-110%). The linear relation was obsd. from 1 to 500 mg/kg for pesticides and 0.3 to 200 mg/kg for PAHs; also, the detn. coeff., R 2, was better than 0.995 in all instances. The proposed method was applied to the routine anal. of PAH and pesticide residues in virgin and refined olive oil and olive-pomace oil samples. 98. Bangma, Chr. H., Grobbee, D. E., and Schroder, F. H. (1995). Volume adjustment for intermediate prostate- specific antigen values in a screening population. *European Journal of Cancer* 31: 12-14.
Chem Codes: Chemical of Concern: PSM Rejection Code: HUMAN HEALTH.

In a screening population of 812 men, between the ages of 55 and 77 years, and prostate-specific antigen (PSA) below 10.0 ng/ml (Hybritech), digital rectal examination (DRE) and transrectal ultrasonography of the prostate (TRUS) were performed. Seventeen prostate carcinomas were detected. Four methods of prostate volumetry were used to determine volume-adjusted PSA levels. These were PSA density for the total gland volume (PSAD), for the inner zone volume (PSAT) and population-specific excess PSA values. There was a significant difference between the benign and the malignant population for age, PSA, PSAD, PSAT and excess PSA values. The maximal discriminatory potential, analysed by the area under receiver ROC curve, was 0.90, reached for prolate spheroid determined excess PSA. For PSA alone this was 0.86. Volume-adjusted PSA values have no additional benefit beyond unadjusted values in screening for prostate carcinoma in this study. prostatic carcinoma/ screening/ PSA/ ultrasonography

Descriptors: Stemonoc oleus
Abstract: Pollen from all 12 and wood from 11 genera in the Crudia group have been examined using light, scanning electron and transmission electron microscopy. This group is currently of systematic interest because it is part of a tribe undergoing taxonomic revision. The pollen grains fall into four groups: (1) Oxystigma, Kingiodendron, Gossweilerodendron, Bathiaea, Neoapaloxylon, Stemonocoleus, Guibourtia and Prioria have pollen of a widespread and generalized caesalpinioid type that are small to medium sized, spheroidal to prolate, tricolporate and with a perforate exine, with some variation in surface ornamentation, aperture margins and ultrastructure. (2) Crudia pollen is tricolporate, coarsely striate with a coarsely scabrate to vermiculate aperture membrane. (3) Augouardia is tricolporate and coarsely reticulate. (4) Hardwickia and Colophospermum are pantoporate and reticulate or microreticulate-rugulate. The wood of Prioria, Oxystigma, Kingiodendron and Gossweilerodendron has diffusely arranged axial canals, and these are four genera that have recently been merged into Prioria. Bathiaea has tangentially arranged axial canals. The other genera lack normal axial canals. Crudia is distinct, with banded parenchyma and variably storied short rays, Augouardia has much less abundant axial parenchyma that is mainly scanty paratracheal and vasicentric, Guibourtia has mainly aliform parenchyma and rays variable in height and width, and Colophospermum and Hardwickia have similar paratracheal parenchyma patterns, although the rays tend to be wider in the latter. Our conclusion is that the Crudia group is not monophyletic. (C) 2000 The Linnean Society of London. 104 refs.

CAS Registry Numbers: 86-50-0 (Azinphos-methyl); 333-41-5 (Diazinon); 732-11-6 (Phosmet); 2642-71-9 (Azinphos-ethyl); 2921-88-2 (Chlorpyrifos); 5598-13-0 (Chlorpyrifos-methyl) Role: ANT (Analyte), ANST (Analytical study) (anal. of organophosphorus pesticide residues by low energy tandem mass spectrometry using electrospray ionization) Electrospray mass spectrometry was used for structural characterization of a series of phosphorothioates and phosphorodithioates and for detection of organophosphorus pesticides. Possible fragmentation routes were first obtained by cone voltage dissocn. Low energy collision-activated dissocn. (CAD) MS/MS analyses of the protonated mol. ion [M+H]+ confirmed the characteristic fingerprint patterns obtained by cone voltage fragmentation for all investigated pesticides and also permitted differentiation of isomeric phosphorodithioates. MS/MS product and precursor ion spectra of selected intermediate fragments provided addnl. structural data and allowed rationalization of the fragmentation routes. Electrospray MS has proved to be a specific and very sensitive method for characterization of organophosphorus pesticides and allowed detection at levels as low as 10 mg/g. CAS Registry Numbers: 52-68-6 (Trichlorfon); 56-38-2 (Parathion-ethyl); 63-25-2 (Carbaryl); 87-86-5; 93-72-1 (Silvex); 93-76-5 (2,4,5-T); 94-75-7 (2,4-D); 95-95-4 (2,4,5-Trichlorophenol); 115-90-2 (Fensulfothion); 120-83-2 (2,4-Dichlorophenol); 122-14-5 (Fenitrothion); 150-68-5 (Monuron); 311-45-5 (Paraoxon); 330-55-2 (Linuron); 732-11-6 (Phosmet); 944-22-9 (Fonofos); 1912-24-9 (Atrazine); 2921-88-2 (Chlorpyrifos); 21725-46-2 (Cyanazine); 23103-98-2; 23135-22-0 (Oxamyl); 49866-87-7 (Difenzoquat) Role: ANT (Analyte), ANST (Analytical study) (detn. of, by thermospray liq. chromatog.-mass spectrometry, eluents for) The influence of different eluents in pos. and neg. ion mode thermospray liq. chromatog.-mass spectrometry was studied with several groups of pesticides, including carbamates, chlorotriazines, phenylureas, phenoxy acids and organophosphorus and quaternary ammonium compds., and the corresponding degrdn. products. Using the pos. ion mode in combination with reversed-phase eluents the base peaks generally corresponded either to [M + H]+ for the chlorotriazines and their hydroxy metabolites or to [M + NH4]+ for the carbamates, the phenylureas, the organophosphorus pesticides and their O analogs. In the neg. ion mode different processes such as (dissociative) electron-capture and anion attachment mechanisms occurred. Fragment ions such as [M - CONHCH3]- for the carbamates, [M - H]- for the chlorotriazines, phenylureas and chlorinated phenoxy acids and [M].bul.-, [M - R]- (R = Me or Et) for organophosphorus pesticides were usually formed. Depending on the

eluent additive used (ammonium acetate, ammonium formate and/or chloroacetonitrile), three different adduct ions were formed: [M + CH3COO]-, [M + HCOO]-, and [M - Cl]+. Normal-phase eluents with cyclohexane, n-hexane and/or dichloromethane provided more structural information and enhanced the response of several compds. The pos. ion mode was useful for the detection of chlorinated phenoxy acids and chlorophenols which could not be detected in the pos. ion mode using reversed-phase systems. The base peaks generally corresponded to [M].bul.+, [M + H]+ or [M - Cl]+. For the characterization of difenzoquat, a quaternary ammonium pesticide of which trace level anal. is troublesome, a post-column ion-pair extn. system was used. An aq. mobile phase with a sulfonate-type counter ion was applied and an extn. solvent contg. cyclohexane-dichloromethane-n-butanol (45:45:10) was used in thermospray liq. chromatog.-mass spectrometry. Illustrative examples of the detn. of residue levels of pesticides in soil matrixes are shown. [on SciFinder (R)] 0021-9673 pesticide/ liq/ chromatog/ mass/ spectrometry

CAS Registry Numbers: 122-14-5 (Fenitrothion); 22248-79-9 Role: ANT (Analyte), ANST (Analytical study) (detn. and behavior of, in rice field); 121-75-5 (Malathion); 298-00-0 (Methyl-parathion); 732-11-6 (Phosmet); 2921-88-2 (Chlorpyrifos); 24017-47-8 (Triazophos) Role: ANT (Analyte), ANST (Analytical study) (detn. of, in rice ecosystem); 7732-18-5 (Water) Role: ANST (Analytical study) (organophosphorus pesticides detn. in, by gas chromatog., of rice ecosystem) A comprehensive anal. protocol for the detn. of organophosphorus pesticides in the biotic and abiotic compartments of a rice crop field (Ebro delta, Spain) is described. This includes two alternative clean-up procedures (Florisil column chromatog. and Bio Beads SX-3 gel permeation chromatog.) and gas chromatog. anal. with nitrogen-phosphorus and mass spectrometric detection. Among the pesticides identified, fenitrothion was the most abundant with residue levels in sediment samples varying from 1-3 mg/g in the first day of application to 0.5 mg/g two days after, whereas in the water canals the concns. were 3-10 mg/L, after aircraft application, with a rapid decrease several hours later. Half lives of fenitrothion in water and sediment samples under natural conditions have been estd. to be lower than 1 day and between 1 and 1.5 days, resp., with volatilization and microbial degrdn. accounting for this decay. The bivalves analyzed in the coastal bays (Tapes semidecussatus, Ostrea edulis and Mytilus galloprovincialis) exhibited residue levels between 20 and 90 ng/g of organophosphorus pesticides, fenitrothion being the most abundant organophosphorus pesticide. These levels are likely in the safe range for bivalves but not for other organisms such as crustacea, which are sensitive to water concns. of 0.1 mg/L. By use of pos. and neg. ion modes (PI and NI, resp.), and the filament-on mode, three different groups of model compds. have been studied: organophosphorus pesticides, chlorophenols, and chlorinated phenoxy acid herbicides. In the PI mode, [M + H]+ was the base peak for the organophosphosphorus pesticides in all solvents, and [M].bul.+, [M - H]+, or [M - Cl]+ were the base peaks for the other compds. depending on the solvent used. In the NI mode, the functional group fragment [FG]-, [M - R]- (R = Me or Et), [M + Cl]-, and [M - HCl]- were the base peaks for the organophosphorus pesticides. Depending on the compd. and the solvent used, [M - HCl]-, [M - H]-, [M + H]- and [M + Cl]- were the base peaks for the chlorophenols and the chlorinated phenoxy acids. The formation of a chloride attachment ion, [M + Cl]-, was more important when cyclohexane or dichloromethane were used as eluents. By use of PI and NI modes under full scan conditions, detection limits in the low nanogram range were obtained. The sensitivity in the PI mode improved 1 order of magnitude compared with previous studies using reversed-phase eluents in TSP LC/MS. Two applications are reported: (1) the anal. of organophosphorus pesticides, using n-hexane-dichloromethane (50:50) as LC eluent, and (2) the use of a postcolumn extn. system with cyclohexane-dichloromethane-1-butanol (45:45:10) as extn. solvent after the ion-suppressed LC sepn. of chlorinated phenoxy acids using acetonitrile-water contg. a nonvolatile buffer. 109. Barron, S., Razani, L. J., Gallegos, R. A., and Riley, E. P. (1995). Effects of Neonatal Ethanol Exposure on Saccharin Consumption. *ALCOHOLISM CLINICAL AND EXPERIMENTAL RESEARCH* 19: 257-261.
Chem Codes: Chemical of Concern: PSM Rejection Code: HUMAN HEALTH.

ABSTRACT: BIOSIS COPYRIGHT: BIOL ABS. Prenatal ethanol exposure has been associated with alterations in a variety of sexually dimorphic behaviors in rats. This study examined the effects of neonatal ethanol exposure on saccharin consumption, a sexually dimorphic behavior in rats. Subjects were Sprague-Dawley rats that were artificially reared (AR) from postnatal day (PN) 4-PN12 through gastrostomy tubes with ethanol exposure limited to PN4-PN10. The AR groups included two ethanol doses (6 g/kg/day and 4 g/kg/day) and an isocaloric maltose-dextrin control. A sham surgery control group was also included. The AR subjects were returned to their dams on PN13. At 21 days of age, subjects were housed with one same-sex sibling and free access to rat chow and water until testing. Subjects were tested for saccharin preference and consumption at 110 days of age. Typically, male rats consume less saccharin than females, and this was evident in the 4 g/kg ethanol group and both control groups. However, this was not appa

110. Barthe, Philippe, Pujade-Renaud, Valerie, Breton, Frederic, Gargani, Daniel, Thai, Robert, Roumestand, Christian, and de Lamotte, Frederic (2007). Structural Analysis of Cassiicolin, a Host-selective Protein Toxin from Corynespora cassiicola. *Journal of Molecular Biology* 367: 89-101.
Chem Codes: Chemical of Concern: PSM Rejection Code: CHEM METHODS, BIOLOGICAL TOXICANT.

Cassiicolin is a host-selective toxin (HST) produced by the fungus Corynespora cassiicola (strain CCP). It is responsible for the Corynespora leaf fall (CLF) disease, which is among the main pathologies affecting rubber tree (Hevea brasiliensis). Working on purified cassiicolin and using electron microscopy, we have demonstrated that this 27-residue O-glycosylated protein is able to induce cellular damages identical to those induced by the fungus on rubber tree leaves and displays the same host selectivity. The solution structure and disulfide pairing of cassiicolin have been determined using NMR spectroscopy and simulated annealing calculations. Cassiicolin appears to have an original structure with a prolate ellipsoid shape. It adopts an over-all fold consisting of three strands arranged in a right-handed twisted, antiparallel [beta]-sheet knitted by three disulfide bonds. Its conformation resembles that found in small trypsine-like inhibitors isolated from the brain, the fat body and the hemolymph of locust grasshoppers. But cassiicolin has no sequence homology with these protease inhibitors, and lacks their characteristic substrate-binding loop. Probably, this motif represents one of the few highly stabilized "minimal" scaffolds, with a high sequence permissiveness, that nature has selected to evolve over different phyla and to support different functions. The knowledge of the 3D structure opens the way to the delineation of the mechanism of action of the toxin using site-directed mutagenesis. ABSTRACT: TD3: The Disposal Area Remedial Action (DARA) Solid Storage Facility (SSF) is a rectangular concrete vault with two high-density Polyethlene (HDPE) liners and covered with a metal building. The SSF was originally designed and constructed to receive saturated sediments from the excavation of the Oil Retention Ponds and Tributary 7 at the Oak Ridge Y-12 Plant. The sediments placed in the SSF were generally high-water-content soils contaminated with polychlorinated biphenyls (PCBs) and volatile organic carbons. The facility was intended to dewater the sediments by allowing the free water to percolate to a 6-in. sand layer covering the entire floor of the facility. The sand layer then drained into sumps located at the east and west ends of the facility. An application for a Part-B Permit was submitted to the state of Tennessee in February 1992 (MMES 1992a). This report is being submitted to support approval of that permit application and to address certain issues known to the regulators regarding this fa

Chem Codes: Chemical of Concern: PSM Rejection Code: CHEM METHODS, BACTERIA.

The length-to-width ratios of bacteriophage T2 and T4 heads and stereometric angles specifying the prolate icosahedral T2 capsid were evaluated on electron micrographs recorded from samples prepared by a variety of methods. The copy numbers of the major capsid protein, gp23*, of T2 and T4 phages were compared by quantitative gel electrophoresis. Taken together, the resulting values are most compatible with triangulation numbers T = 13 and Q = 21 for both T2 and T4, thus

confirming the previously proposed capsid architecture of T4 revealed by indirect measurements and thereby eliminating the repeatedly reported discrepancy between T2 and T4 in favor of a common Q number of 21 corresponding to 960 copies of gp23*.

114. Baum, Oliver, Esser, Simone, Gierse, Niels, Brunken, Sandra, Lewen, Frank, Hahn, Josef, Gauss, Jurgen, Schlemmer, Stephan, and Giesen, Thomas F. (2006). Gas-phase detection of HSOD and empirical equilibrium structure of oxadisulfane: SPECTROSCOPY WITH AN ASTRONOMICAL FOCUS: EXPERIMENTAL AND THEORETICAL STUDIES OF SMALL MOLECULES: - A Collection of Invited Papers in Honor of Professor Gisbert Winnewisser on the Occasion of his 70th Birthday. *Journal of Molecular Structure* 795: 256-262.
Chem Codes: Chemical of Concern: PSM Rejection Code: CHEM METHODS.

We present the first gas phase spectra of singly deuterated oxadisulfane, HSOD, in its vibrational ground state. More than 100 transitions have been recorded with highest frequency accuracy using the Cologne Terahertz Spectrometer. The molecular parameters derived from a least squares fit analysis proof HSOD to be an almost accidental symmetric prolate top molecule with an asymmetry parameter [kappa]=-0.9985. Spectra of c-type and weaker b-type transitions have been recorded in the range from 716 to 772 GHz. The ratio of the dipole moments [mu]c/[mu]b=2.4(3) has been derived from measured line intensities. The c-type transitions are split by the tunneling motion of a hindered internal rotation, whereas b-type transitions show no splitting within the Doppler limited line profiles. We derived the equilibrium molecular structure of oxadisulfane, HSOH, from experimental values of the rotational constants A0, B0, and C0 of HSOH, H34SOH, DSOD, and HSOD. The equilibrium rotational constants Ae, Be, and Ce were derived by taking vibration-rotation interaction constants [alpha]r obtained from high-level ab initio calculations into account. Chem Codes: Chemical of Concern: PSM Rejection Code: FATE, CHEM METHODS.

ABSTRACT: BIOSIS COPYRIGHT: BIOL ABS. The Standard Leaching Test (SLT) is drafted in order to make an estimate of the metal emission from metal contaminated waste-materials. A modification of SLT is developed and tested for research of the leaching behaviour of hydrophobic organic compounds. It encompasses the leaching procedure, treatment and enrichment of the percolate fractions. A cartridge sampling technique is described for the collection of polycyclic aromatic hydrocarbons (PAH) from the percolates. The modified SLT is applied successfully on two environemental samples, polluted with PAH. Data from the SLT are used to classify waste materials according to Dutch governmental regulations dealing with re-use and landfilling.

Chem Codes: Chemical of Concern: PSM Rejection Code: BACTERIA.

ABSTRACT: BIOSIS COPYRIGHT: BIOL ABS. Organic extracts (dichloromethane) isolated

from airborne particulate matter, collected in two sampling sites located in the Barcelona City, were mutagenic in the Salmonella typhimurium (TA98 +/-S9) bioassay. The highest direct-acting mutagenicity (69-78 rev m-3) was during fall and spring, which corresponds to the highest levels of mutagenic nitroarenes (248 to 350 pg m-3). On the other hand, the highest level of indirect-acting mutagenicity was obtained in summer, paralleling with the highest concentrations of polycyclic aromatic ketones and polycyclic aromatic quinones. Furthermore, the sources of PAH in the urban particulate matter were estimated from the ratio of the less reactive components (i.e. benzofluranthenes/benzo(e)pyrene, indeno(1,2,3-cd)pyrene/benzo(ghi)perylene, methylphenantherenes/phenanthrene) and reflected a predominance of pyrolytic mobile sources (i.e. vehicular emissions). Nevertheless, a contribution of stationary sources in winter was also appa

117. Bechtold, D. B. and Pacquet, E. A. (Bench Scale Saltcake Dissolution Test Report. *Govt reports announcements & index (gra&i), issue 10, 2003*.
<u>Chem Codes</u>: Chemical of Concern: PSM <u>Rejection Code</u>: CHEM METHODS.

ABSTRACT: Prepared in cooperation with Numatec Hanford Corp., Richland, WA. Sponsored by Department of Energy, Washington, DC. Assistant Secretary for Environmental Management.
ABSTRACT: A potential scenario for retrieving saltcake from single shell tanks is the 'Rainbird(Registered trademark) sprinkler' method. Water is distributed evenly across the surface of the saltcake and allowed to percolate by gravity through the waste. The salt dissolves in the water, forming a saturated solution. The saturated liquid is removed by a saltwell pump situated near the bottom of the tank. By this method, there is never a large inventory of liquid in the tank that could pose a threat of leakage. Exploratory laboratory bench-scale tests were completed to evaluate physical and chemical parameters associated with dissolution of a simulated Hanford saltcake waste by this method. This task was performed for, and in collaboration with, River Protection Project (RPP) Retrieval Engineering, Retrieval System Development. This work was

funded by the Tanks Focus Area (EM-50) under Technical Task Plan Number RL09WT22 and satisfies Milestone A. 1-3, 'Perform Saltcake Dissolution Retrieval Tests'.

118. Becker, M. and Raasch, U. (Sustainable Rainwater Management in the Emscher River Catchment Area. *Water sci technol. 2002; 45(3):159-66. [Water science and technology : a journal of the international association on water pollution research]: Water Sci Technol.*
Chem Codes: Chemical of Concern: PSM Rejection Code: FATE.

ABSTRACT: The wastewater management system of the Emscher region is currently being radically restructured. The receiving waters currently surviving as open sewers are to be freed of their wastewater burden and reconstituted to a state as natural as possible, while the wastewater is to be routed underground to the treatment plants. Great importance is attached to the most natural possible rainwater management, in order to buffer extreme run-off situations in the watercourses and to minimize the costs for residential-area water management engineering. Rethinking, which in many cases percolates through only slowly, is necessary in many respects for this purpose. A contest has been set up in the Emscher catchment area in order to accelerate this in the existing residential areas. Seepage, decentralized retention, disconnection and discharge into bodies of water and watercourses have been financially supported. The results are presented and the further procedure deriving from them discussed.

ABSTRACT: PESTAB General problems of the hygienic standardization of pesticide residues in food products are outlined. Studies on the possibility of substituting other, environmentally less problematic pesticides for DDT and studies on the significance of organomercurial fungicide residues in the crops and the soil are described. Continual updating of existing tolerance lists for food products; elaboration of tolerance lists for animal feed, water, air in residential areas and in workplaces; specification of waiting periods before harvesting; and standardization of analytical methods for the determination of residues of plant protection agents and growth regulators in food products, animal feed, and water are required for an effective hygienic control of pesticide residues. Various pesticide preparations and possible substitutes for DDT were tested for persistence in pea cultures. Lindane, butonate, trichlorfon, dimethoate, imidan, and methyl parathion were highly efficient and had relatively low persistence in the soil as well as in pea plants and seeds. The ban imposed on the use of organomercurials as seed dressing agents in various countries is considered unnecessary since no significant difference in the mercury levels in grains grown from dressed and undressed seeds due to the absorption of natural mercury

resources from the soil was determined.

122. Belin, P. and Boquet, P. L. (The Escherichia Coli Dsba Gene Is Partly Transcribed From the Promoter of a Weakly Expressed Upstream Gene. *Microbiology. 1994, dec; 140 (pt 12):3337-48. [Microbiology (reading, england)]: Microbiology*.
Chem Codes: Chemical of Concern: PSM Rejection Code: BACTERIA.

ABSTRACT: The dsbA gene of Escherichia coli encodes a periplasmic enzyme which catalyses disulfide bond formation. Analysis of its surrounding DNA region showed that it is preceded by an open reading frame, orfA, of 984 nucleotides. The intergenic region (19 nucleotides) carries no typical transcription termination signals. dsbA is transcribed from two promoters, the first (P1) lies in the distal part of orfA, and the second (P2) just upstream from orfA. Using a plasmid-borne dsbA::TnphoA fusion and an orfA::omega insertion, each promoter was shown to contribute equally to dsbA transcription. The disruption of the single chromosomal copy of orfA by omega more drastically reduced the amount of DsbA in the periplasmic space. Such a reduction of the DsbA pool, however, did not change the activities of the AppA, Agp and PhoA periplasmic phosphatases, which all require disulfide bond formation, even when the enzymes were produced from multicopy recombinant plasmids. Thus, in a wild-type strain, DsbA is far from being in limiting amounts for physiological requirements. The orfA gene product was identified as a weakly expressed 39 kDa cytoplasmic protein, but it is not involved in the overall mechanism of disulfide bond formation.

The authors used enzymic activity of chloroperoxidase on the metab. of some phosphorothioate pesticides published previously and mol. mechanics methods to perform a theor. approach of the mechanism of biol. oxidn. of this class of pesticides. The mol. structure of eight pesticides were optimized by mol. mechanics methods using the CAChe program package for biomols., ver. 3.11 (Oxford Mol. Ltd., Campbell, CA). Total energy resulted from the structure optimization process and the partial charges of both phosphorus and sulfur were computed for every pesticide. Phosphorus partial charge and enzymic activity were significantly related by linear regression anal. ($r=0.82$, $P<0.05$). Analyzing our results and using previously reported enzymic activity of chloroperoxidase on these pesticides, we deduced chem. events involved in activation of the active site of chloroperoxidase and proposed a novel mechanism of oxidn. for this class of pesticides. This mechanism will also help to understand the oxidn. process of pesticides by cytochrome P 450, and prodn. of toxic metabolites. 129. Bergstrom, L. (1990). Leaching of Dichlorprop in Sand and Clay Soils Measured in Field Lysimeters. *Swed j agric res* 20: 115-120.
Chem Codes: Chemical of Concern: PSM Rejection Code: FATE.

ABSTRACT: BIOSIS COPYRIGHT: BIOL ABS. Leaching of the herbicide dichlorprop (2-(2,4-dichlorophenoxy)propionic acid) was studied in field lysimeters filled with either a sandy soil or a

clay soil. The herbicide was applied at a rate of 1.5 kg a.i./ha, representing a normal dose for spring cereals. Four out of eight lysimeters received supplementary watering in addition to natural rainfall. Dichlorprop concentrations above the detection limit (0.1 mug/l) were observed on one sampling occcasion in the clay lysimeters and on three occasions in the sand lysimeters, reaching 16 and 26 mug/l in percolate from the respective soils. In both soils, peak concentrations occurred after less than 3 mm of drainage had been collected. Converted to fluxes over the 7-month period, a maximum of 0.13% of the applied dichlorprop appeared in percolate. These results suggest that the peak concentrations (> 15 mug/l) of dichlorprop found in Swedish stream waters can only be explained by considering additional transport pathways

130. Berkane, K. , Caissie, G. E., and Mallet, V. N. (The Use of Amberlite Xad-2 Resin for the Quantitative Recovery of Fenitrothion From Water--a Preservation Technique. *J. Chromatogr. 139(2): 386-390 1977 (8 references).*
Chem Codes: Chemical of Concern: PSM Rejection Code: CHEM METHODS.

ABSTRACT: PESTAB. The usefulness of Amberlite macroreticular resins for quantitative recovery of various organic contaminants from environmental water has been investigated. A multiresidue technique has been developed using these resins to extract organochlorine pesticides and polychlorinated biphenyls from natural waters. Water samples containing fenitrothion were allowed to percolate down a column of Amberlite XAD-2 resin, then the column was eluted with an appropriate organic solvent and the fenitrothion retained was determined by TLC analysis or GLC. The recovery of fenitrothion from distilled water averaged 94% according to in situ fluorometry; the results were confirmed by GLC in experiments with natural water. Fenitrothion degradation was not important within 10 days of the fluorometry experiment, and no degradation was apparent by GLC over a 5-week period. Thus the fenitrothion was stable on the column and the method can be used as a preservation technique. The water sample containing fenitrothion can be processed in the field, and the column can be eluted and its contents analyzed some time afterwards.

131. Berkane, K. , Caissie, G. E., and Mallet, V. N. (The Use of Xad-2 Amberlite Resin for the Quantitative Recovery of Fenitrothion From Water - a Preservation Technique. *In: proceedings of a symposium on fenitrothion: the long-term effects of its use in forest ecosystems. Roberts, j. R., Greenhalgh, r., And marshall, w. K., Eds. (Natl. Res. Council can.: Ottawa, canada) nrcc no. 16073: 95-103 1977 (8 references).*
Chem Codes: Chemical of Concern: PSM Rejection Code: CHEM METHODS.

ABSTRACT: PESTAB. The use of an Amberlite resin (XAD-2) for the recovery of fenitrothion from water is described. A glass column was filled with distilled water, and the resin in a water slurry was added with the stopcock open to obtain the desired column length. A 1-l water sample containing 50 mug/l of fenitrothion was allowed to percolate down the column. The column was then eluted with an organic solvent such as ethyl ether or ethyl acetate. The eluted sample can then be concentrated for TLC or fluorometric analysis, or made up to 50 ml in a flask for gas chromatogrphic analysis. The fenitrothion is stable in the resin column, so that this method can be used as a preservation technique. The environmental water sample containing fenitrothion can be processed in the field and the column can be eluted and its content analyzed some time afterwards. During this time fenitrothion remains unchanged in the column. Greater than 90% recoveries were obtained for the 50 ppb sample using this technique.

data were obtained from an openly available toxicol. database and were selected to be representative of a single endpoint. A large no. of physicochem. and structural descriptors were calcd. for the pesticides. QSAR models were developed using multiple linear regression and partial least squares analyses. Following the removal of a small no. of outliers, predictive QSARs were developed on small nos. of mechanistically relevant descriptors. Applying mechanistic knowledge to the development of QSAR further improved predictivity. [on SciFinder (R)] 1526-498X toxicity/ organophosphorus/ carbamate/ pesticide/ rainbow/ trout/ Onchorhynchus

An investigation of the use of the chromatog. retention (log k) in biopartitioning micellar chromatog. (BMC) as an in vitro approach to evaluate the toxicity in fish of pesticides (acute toxicity levels as pLC50) is proposed. A heterogeneous data set of 85 pesticides from six chem. families with available exptl. fish toxicity data (ECOTOX database from U.S. Environmental Protection Agency (EPA)) was used. For pesticides exhibiting non-polar narcosis mechanism in fish (non-specific toxicity), more reliable models and precise pLC50 estns. are obtained from log k (quant. retention-activity relationships, QRAR) than from log P (quant. structure-activity relationships, QSAR) or ECOSAR (ECOSAR program from U.S. EPA). (BMC) as an in vitro approach to evaluate the bioconcn. factor (BCF) of pesticides in fish is proposed. A heterogeneous set of 85 pesticides from six chem. families was used. For pesticides exhibiting bioconcn. in fish (exptl. log BCF > 2), a quant. retention-activity relationships (QRAR) model is able to perform precise log BCF estns. of new pesticides. Considering the present data, the results based on log k seem to be more reliable than those from available software (BCFWIN and KOWWIN) and from log P (quant. structure-activity relationships (QSAR)). It is also possible to perform risk assessment tasks fixing a threshold value for log k, which substitute two common threshold values, log P and exptl. log BCF, avoiding the exptl. problems related with these two parameters. ABSTRACT: BIOSIS COPYRIGHT: BIOL ABS. We have previously evaluated the measurement of viability and cytokine release from skin equivalents, for predicting the skin irritation potential of topically applied surfactants and demonstrated that IL-1alpha and interleukin-1 receptor antagonist (IL-1ra) release from epidermal skin equivalents correlates with skin irritation potential. In this study, the utility of the model was confirmed by the evaluation of cleansing bars and cleansing lotions that exhibited varying degrees of irritation p uman irritation data, demonstrating that the model can correctly predict the irritation potentialof soap and surfactant products. These results show that this in vitro model is useful for rank ordering the irritation potential of mild consumer products and for demonstrating enhanced mildness in products with minor differences.

The popularity of gas chromatog. for pesticide residue anal. stems from the use of the highly specific detectors (electron capture, thermionic), which lessen or eliminate the need for time-consuming cleanup of samples before anal., yet respond to subnanogram amts. of the residues. The flame-photometric detector for P and S compds. is such a device; it has proved effective in the anal. of about 100 pesticides and their metabolites in a great variety of substrates. With residues of certain pesticides producing as many as 5 metabolites, the compds. have been detd. individually; they have also been oxidized to a single compd., thus speeding anal. of the total residue. A dual flame-photometric detector was devised to det. simultaneously P and S compds. as well as the at. ratio of these elements in a mol. A fiber-optic scanner for detg. pesticide residues quant. by thin-layer chromatog. is also described. This adsorption results in low recoveries of nonpolar pesticides in extns. with hexane-ether (1:1) carried out immediately after spiking and 5 hrs. later. Recoveries from raw and pasteurized homogenized milk by an extn. procedure that gives low fat recovery parallel the polarities of the pesticides. Recoveries by an extn. procedure that gives high fat recovery were satisfactory. With the most polar of the pesticides, recoveries by the extn. procedure giving low fat recovery consistently exceeded those by the procedure giving high fat recovery. Although the data indicate that added pesticides are adsorbed on the fat globule, the nonpolar pesticides may also be bound in the aq. phase of the milk after removal of the cream. ABSTRACT: The overall objective of this paper is to present an extensive set of data for corrosion-induced copper dispersion and its environmental interaction with solid surfaces in the near vicinity of buildings. Copper dispersion is discussed in terms of total copper flows, copper speciation and bioavailability at the immediate release situation, and its changes during transport from source to recipient. Presented results are based on extensive field exposures (eight years) at an urban site, laboratory investigations of the runoff process, published field data, generated predictive site-specific runoff rate models, and reactivity investigations toward various natural and manmade surfaces, such as those in soil, limestone, and concrete. Emphasis is placed on the interaction of copper-containing runoff water with different soil systems through long-term laboratory column investigations. The fate of copper is discussed in terms of copper retention, copper chemical speciation, breakthrough capacities, and future mobilization based on changes in copper concentrations in the percolate water, computer modeling using the Windermere Humic Aqueous Model, and sequential extractions. The results illustrate that, for scenarios where copper comes in extensive contact with solid surfaces, such as soil and limestone, a large fraction of released copper is retained already in the immediate vicinity of the building. In all, both the total copper concentration in runoff water and its bioavailable part undergo a significant and rapid reduction.

Abstract: This paper comprises data from an extensive cross-disciplinary research project aiming to elucidate the environmental fate of corrosion-induced zinc release from external structures. It includes an exposure assessment that provide long-term runoff rates, concentrations and chemical speciation of zinc, from 14 zinc-based materials exposed during 5 years in Stockholm, Sweden, and an effect assessment including bioavailability and ecotoxicity measurements, both at the immediate release situation and after soil interaction. Runoff rates of total zinc ranged from 0.07 to 2.5 g Zn m super(- 2) yr super(- 1) with zinc primarily released as the free ion for all materials investigated. The average effect concentration, causing a 50% growth reduction after 72 h to the green algae Raphidocelis subcapitata, was at the immediate release situation 69 mu g Zn L super(- 1). Upon interaction of runoff water with soil, which simulated 18 to 34 years of exposure, the total zinc concentration was significantly reduced, from milligram per litre to microgram per litre levels. Simultaneously, the most bioavailable fraction of zinc in runoff, the hydrated zinc(II)-ion, decreased from more than 95% to about 30%. The major fraction, 98-99%, of the introduced total zinc concentration in the runoff water was retained within the soil. As long as the soil retention capacity was not reached, this resulted in zinc concentrations in the percolate water transported through the soil layer, close to background values and below growth inhibition concentrations for the green algae investigated. Zinc retained in soil was to a large extent (85-99.9%) extractable with EDTA, and available for plant uptake after 5 to 7 months of ageing.

Chem Codes: Chemical of Concern: PSM Rejection Code: CHEM METHODS.

A method has been developed to measure the cell volume of the unicellular, green alga Dunaliella bioculata 19/4 during salt stress conditions, where shape change in the alga becomes problematic and the cells can no longer be recognised as 'prolate ellipsoids', by using image analysis of transmission electron micrographs. The image analysis of the micrographs employs a specialised numerical integration programme or 'variable frames analysis' for unicellular microorganisms which possess a single axis of symmetry. Basic mathematics was used to determine: (a) the functional dependence of the calculated volume on the angle of the cut to the axis of symmetry and the distance of the origin of the cut from the centre of mass; (b) errors resulting from the orientation of the longest axis off-vertical for image analysis; (c) the uppermost range of calculated volumes obtained which represent the 'true' volumes within required confidence levels. The procedure was applied to a series of experiments on the effects of salt stress on Dunaliella bioculata cells. Abstract: Quantifying temporal changes in soil temperature and moisture conditions is an important part of characterizing pre- and post-disturbance conditions that influence the health, productivity, and sustainability of forest ecosystems. In this paper, we present an experimental case study that was used to evaluate the ability of the forest hydrology model ForHyM2 to simulate field-observed changes in root-zone soil moisture and temperature, as well as snowpack depth, throughfall volume and forest floor percolate volume, for a jack pine (Pinus banksiana Lamb.) site in northeastern Ontario. The experiment refers to two post-harvest treatment factors, each involving two treatments: (a) blading (removing) or non-blading the forest floor and part of the mineral topsoil, (b) herbiciding or non-herbiciding. It was found that harvesting increased the average daily soil temperature by 4-6(degrees)C on all treatment plots during summer (5 cm soil depth). Blading increased the soil temperature further by 1-2(degrees)C. Herbiciding did not have significant effects on soil temperature. Eliminating competing forest vegetation significantly increased soil moisture level on the non-bladed treatment plots. The model simulations were based on daily precipitation (snow and rain), air temperature, and a few site descriptors such as longitude and latitude, soil depth, soil texture, and leaf area index. The resulting simulations compared well (graphically) with the pre- and post-harvest field observations regarding soil moisture, soil temperature, and snowpack water equivalents. Good graphical agreements suggest that the approach taken with this case study can be applied to the evaluation of soil moisture and temperature conditions to a variety of pre- and post-disturbance forest conditions, The results from the study would be useful for addressing below ground processes such as root growth, soil respiration, rate of organic matter decomposition, rate of soil weathering, nutrient cycling, etc., all of which strongly influence site productivity. 145. Bielders, C. L. and Baveye, P. (1995). Vertical particle segregation in structural crusts: experimental observations and the role of shear strain. *Geoderma* 67: 247-261.
Chem Codes: Chemical of Concern: PSM Rejection Code: CHEM METHODS.

There is ample evidence that coarse-textured soils can be highly sensitive to crust formation under rainfall. One of the most controversial aspects of crust formation on such soils is the frequent occurrence of a thin clay band buried below a washed-out layer. In order to better understand the mechanisms that may lead to this vertical sorting in structural crusts, mixtures of 92.5% sand and 7.5% clay were exposed to simulated rainfall for 1 h at 63 mm h-1. The sand fraction of the samples consisted of a binary mixture of contrasting particle-size classes between 106 and 1000 [mu]m, mixed in varying proportions. Micromorphological changes in surface structure were observed on thin sections made from undisturbed samples. Before rainfall, the clay was present as coatings around the sand grains. In all samples subjected to rainfall, a washed-out layer 2 to 2.5 mm thick formed at the soil surface. Except for the samples containing 50% or more 106-150 [mu]m sand, the lower boundary of the washed-out layer was marked by an accumulation of clay material, generally in the form of a band. This clay material was present as microaggregates that were probably derived from the initial grain coatings. Within the washed-out layer a vertical sorting of the sand grains was sometimes observed, which resulted in a relative concentration of the coarsest particles at the surface. The sorting was more pronounced as the ratio between the diameter of the large and small sand grains increased, and as the relative percentage of finer sand decreased. By analogy with a physical model derived for particle segregation in granular media, it is proposed that the vertical sorting of particles according to their size was caused by the shear strain created in the first few millimeters of the samples by drop impact. The strain is believed to have induced temporary changes in pore size which allowed the preferential downward movement of finer grains that would otherwise riot percolate freely. The present observations suggest that strain-induced segregation may be one of the main mechanisms leading to clay band formation in structural crusts formed on coarse-textured soils. The implications of the model are discussed in terms of the range of conditions under which segregation is expected to occur. The experimental results also point to the distinctive role of the particle-size distribution of the sand fraction on the morphology of structural crusts. http://www.sciencedirect.com/science/article/B6V67-4002HT6-B/2/105e3a4b9fb247664924697997df3365

ABSTRACT: TD3: In connection with the national soil protection law (Bundesbodenschutzgesetz), it is planned for risk assessment to estimate concentrations of contaminants in soil water according to the preliminary standard DIN V 19736. In this standard, a

method is described for percolation of soil samples. In this DGMK project, the current draft was applied to soil samples which are contaminated with mineral oil. Another aim of the project was to find a correlation between the soil concentrations and the percolate concentrations. The most important results of this project are: Soil contaminations with gasoline will be easily percolated than contaminations with Diesel fuel or lubricants. No correlation between the concentrations of mineral oil in soil and in percolate could be found. The procedure described in the preliminary standard is not useful for a sophisticated assessment of mineral oil contaminations in soils.

Abstract: Chromosome numbers, karyotypes, meiotic behaviour and pollen analysis are presented for species of Chamaecrista Moench (Leguminosae, Caesalpinioideae, Cassieae) native to southern Brazil: C. nictitans ssp. patellaria, C. nictitans ssp. disadena, C. repens, C. rotundifolia, C. flexuosa, C. vestita and C. desvauxii. Meiotic behaviour is reported for the first time for all the taxa and was very regular; only bivalents were formed at diakinesis and metaphase I, chromosome disjunction and segregation were regular at anaphases I and II, meiotic indexes were over 99% and pollen fertility was over 92%. Pollen grains were subprolate in C. flexuosa and C. vestita and prolate-spheroidal in the other taxa. Karyotypes were symmetrical in all six species and the data are original, except for C. nictitans ssp. patellaria. Chromosome number is presented for the first time for C. repens (2n = 16) and has been confirmed for the other taxa: 2n = 14 for C. desvauxii, 2n = 32 for the tetraploid C. nictitans ssp. patellaria and C. nictitans ssp. disadena, and 2n = 16 for the other species. These two basic numbers found in the genus, x = 7 and x = 8, point to chromosome evolution by dysploidy, which has also been accompanied by polyploidy. (copyright) 2006 The Linnean Society of London.

Citations: 43) Stromberg, K; Chemistry in Ecology 1984, 2, 39 Egg fertility, clutch size and egg and chick survival and pesticide exposure of tree swallows (Tachycineta bicolor) and eastern bluebirds (Sialia sialis) were measured annually using nest boxes in sprayed and nonsprayed apple orchards in southern Ontario, Canada, during 1988-1994. Assocns. were examd. between reproductive rates and historical organochlorine residues in eggs as well as the degree of exposure and toxicity of pesticides applied during the study period. Because many pesticides in current use are not persistent in wildlife tissues, a toxicity score was developed to describe the exposure for each nest. The toxicity score was calcd. as the product of the extent of the orchard sprayed and the application rate of the chems., divided by an acute reproductive toxicity index of each chem. Total organochlorine concns. in tree swallow eggs were 0.74 to 3.47 mg/g, and in eastern bluebird eggs, these values ranged from 0.47 to 106.3 mg/g. More than 90% of the residue in eggs was pp'DDE. There was a significant increase in unhatched eggs in bluebirds as organochlorine levels increased in eggs. There were significant assocns. between toxicity scores of current-use pesticides and at least one avian reproductive parameter in every year of the study, but the redn. in productive rates assocd. with pesticides did not exceed 14%, for either species, in any year. Reduced reprodn. occurred in 6 yr in tree swallows but for bluebirds, this occurred in only 4 yr. [on SciFinder (R)] 0730-7268 pesticide/ reproductive/ toxicity/ bird/ apple/ orchard

Citations: Yadav, A; Ecotoxicol Environ Safety 1987, 12, 97 To investigate the effects of pesticides on wild birds, sex (17b-estradiol; testosterone) and thyroid (triiodothyronine, T3) hormone concns., body mass, and testes mass were measured and the development of testes was evaluated in wild tree swallows (Tachycineta bicolor) nesting in four sprayed apple orchards and three nonsprayed sites in southern Ontario, Canada, in 1995-1996. In orchards, birds were exposed to as many as 11 individual spray events and five sprays of mixts. of chems. Residues of organochlorine pesticides, PCBs, lead, and arsenic concns. were low and not variable among sites except p,p'-DDE concns., which ranged from 0.36 to 2.23 mg/g wet wt. in eggs. These persistent compds. were not correlated with any endocrine response measured in tree swallows. In 16-d-old male tree swallow chicks, body mass and concns. of 17b-estradiol (estradiol), testosterone, and T3 in plasma showed no significant differences between sprayed and nonsprayed groups and among sites within those groups. However, T3 concns. were slightly elevated in the sprayed group compared to the nonsprayed group, and there was a significant and pos. correlation between T3 and the no. of mixts. of sprays applied during egg incubation through chick rearing. In 16-d-old female chicks, there were no significant differences among spray treatments or sites and no correlations with spray exposure for testosterone, estradiol, or T3 in plasma. Body mass was correlated pos. with T3 and neg. with estradiol but showed no differences among spray exposure groups or sites. Histol. of testes of 16-d-old male chicks indicated there were no significant differences among sprayed and nonsprayed birds in testes mass, area, or diam., or the presence of Leydig cells in the interstitium, the distribution of the Sertoli cells, or the occurrence of heterophils in the testicular interstitium. For the percentage of spermatogonia present on the basement membrane, there were significant differences among sites, but these differences were not specifically assocd. with spray exposure. However, there was a marginally significant trend between increasing occurrence of a disrupted Sertoli cell population on the seminiferous tubular basement membranes as the no. of mixts. of pesticides sprayed during chick rearing increased. In adult male and female parent tree swallows, there were no differences in hormone concns. between birds from sprayed and nonsprayed sites. Nor were there any significant correlations between the concn. of any hormone and collection date, body mass, or any type of spray exposure for adults. The correlations between increasing pesticide exposure and abnormal thyroid hormone and testes development in male chicks indicate that further redns. of pesticide use in orchards may benefit the health of birds that nest there. However, it is unclear which of these pesticides or spray mixts. are responsible for these effects, and this needs to be examd. in future studies. Citations: 30) Instituto Nacional de Estadistica; http://www.ine.es/ 2001 Fifty samples of honey collected from local markets of Portugal and Spain during year 2002 were analyzed for 42 organochlorine, carbamate, and organophosphorus pesticide residues. An anal. procedure based on solid-phase extn. with octadecyl sorbent followed by gas chromatog.-mass spectrometry (GC-MS), for organochlorines, and by liq. chromatog.-atm. pressure chem. ionization-mass spectrometry (LC-APCI-MS), for organophosphorus and carbamates, was developed. Recoveries of spiked samples ranged from 73 to 98%, except for dimethoate (40%), with relative std. deviations from 3 to 16% in terms of repeatability, and from 6 to 19% in terms of reproducibility. Limits of quantification were from 0.003 to 0.1 mg kg-1. Most of the pesticides found in honey were organochlorines. Among them, g-HCH was the most frequently detected in 50% of the samples, followed by HCB in 32% of the samples and the other isomers of HCH (a-HCH and b-HCH) in 28 and 26% of the samples, resp. Residues of DDT and their metabolites were detected in 20% of the samples. Of the studied carbamates, both methiocarb and carbofuran were detected in 10% of the samples, pirimicarb in 4% and carbaryl in 2%. The only organophosphorus pesticides found were heptenophos in 16%, methidathion in 4%, and parathion Me in 2% of honey samples. Results indicate that Portuguese honeys were more contaminated than Spanish ones. However, honey consumers of both countries should not be concerned about the amts. of pesticide residues found in honeys available on the market. Time Course of Copper Elution and Characterization of Reactive Binding Forms. *Zeitschrift fuer pflanzenernaehrung und bodenkunde* 160: 393-400.
<u>Chem Codes</u>: Chemical of Concern: PSM <u>Rejection Code</u>: FATE.

ABSTRACT: BIOSIS COPYRIGHT: BIOL ABS. A copper contaminated (Cu content: 294 mg kg-1) soil material sampled from an area formerly cultivated with hops (Humulus lupulus), was extracted within sixteen days in a column test facility (soil packing percolumn: 4.1 kg dry weight) by the percolation of an amino acid containing blood meal hydrolysate. The objectives of the study were to record the time course of copper elution, to determine the resulting degree of copper removal and to examine the specific extractability of the various copper binding forms. Until the maximum Co concentration in the column effluent was reached, the time course of the Cu release went parallel to the throughput of the amino acids. As a consequence, the velocity of the copper mobilization and transport seems to be ruled by the hydrodynamic flux of the percolate mainly. In total 62% of the soil bound copper were removed by the hydrolysate. Above-average amounts were extracted from the binding forms 2-4 defined according to Zeien and Brum

(Gaba(B) Receptors as Potential Targets for Drugs Able to Prevent Excessive Excitatory Amino Acid Transmission in the Spinal Cord. *Eur j pharmacol. 1998, dec 4; 362(2-3):143-8. [European journal of pharmacology]: Eur J Pharmacol.*
Chem Codes: Chemical of Concern: PSM Rejection Code: IN VITRO.

ABSTRACT: The effects of GABA(B) receptor activation on the Ca2+-dependent depolarization-induced overflow of endogenous glutamic acid and gamma-aminobutyric acid (GABA) was studied in rat spinal cord nerve terminals exposed in superfusion to 15 mM KCl. The GABA(B) receptor agonist (-)-baclofen inhibited the K+-evoked overflow of glutamate (EC50=0.098 microM) but was almost inactive against that of GABA. The overflow of both transmitters could

be quite similarly inhibited by two other GABA(B) receptor agonists, 3-APPA (3-aminopropylphosphonous acid; EC50=0.087 and 0.050 microM in the case of GABA and glutamate, respectively) and CGP 44532 (3-amino-2(S)-hydroxypropyl)methylphosphinic acid; EC50=0.81 and 0.50 microM). The GABA(B) receptor antagonist CGP 35348 [3-amino-propyl(diethoxymethyl)phosphinic acid] blocked the effect of 3-APPA (1 microM) at the autoreceptors (IC50 approximately = 1 microM), but not at the heteroreceptors. In contrast, the effects of 3-APPA at both autoreceptors and heteroreceptors could be similarly prevented by another GABA(B) receptor antagonist, CGP 52432 [3-[[(3,4-dichlorophenyl)methyl]amino]propyl](diethoxymethyl) phosphinic acid (IC50 approximately = 10 microM). The data suggest that, in the spinal cord, GABA(B) autoreceptors on GABA-releasing terminals differ pharmacologically from GABA(B) heteroreceptors on glutamatergic terminals. Selective GABA(B) receptor ligands may be helpful for conditions characterized by excessive glutamatergic transmission in the spinal cord.

ABSTRACT: Normally, the transport of allergens through the intestinal epithelia to the blood is limited. It is hypothesised that if these compounds arrive in the blood circulation, they must percolate through the epithelial cell layer. Thus, food allergy (and thus atopic eczema) implies an increased intercellular leakage of the gut wall. Such increased intercellular leakage is thought to be caused by a slightly changed cellular morphology due to a slight cytopathologic effect because of both a limited decay of the cytoskeleton and a slightly reduced turgor. These events may be due to a reduced production of intracellular metabolic energy in the epithelial cells due to an increased concentration of familiar, frequently occurring, potentially toxic bacterial metabolites, i.e., d-lactic acid and/or ethanol. In this hypothesis we suggest that adequate probiotics can (i) prevent the increased characteristic intestinal permeability of children with atopic eczema and food allergy, (ii) can thus prevent the uptake of allergens, and (iii) finally can prevent the expression of the atopic constitution. The use of adequate probiotic lactobacilli, i.e., homolactic and/or facultatively heterolactic l-lactic acid-producing lactobacilli, reduces the intestinal amounts of the bacterial, toxic metabolites, d-lactic acid and ethanol by fermentative production of merely the non-toxic l-lactic acid from glucose. Thus, it is thought that beneficial probiotic micro-organisms promote gut barrier function and both undo and prevent unfavourable intestinal micro-ecological alterations in allergic individuals.

157. Borsuk, O. P. (Development of Resistance in the Colorado Beetle to Some Insecticides. *Khim. Sel'sk. Khoz. 1: 56-58* 1976..
Chem Codes: Chemical of Concern: PSM Rejection Code: NON-ENGLISH.

ABSTRACT: PESTAB. Development of resistance in the Colorado beetle to pesticides of different chemical types (DDT, strobane, trichlorfon) was studied in 2 regions of the Ukraine. For this purpose, the imago of the beetle was collected and individuals were exposed to acetone solutions of the pesticides. The number of insect deaths was counted for 24, 48 and 72 hr after placement of the insecticide solutions on their bodies. The mean values of LD50, the confidence range, and the regression coefficient were established. The observations indicated reduced sensitivity of the pest to organochlorine compounds. There was a 46-fold rise in insect resistance to DDT from 1963 to 1974, a 9-fold rise for polychloropinene, (strobane) and no changes were seen regarding sevin (carbaryl) and chlorophos (trichlorfon) in the Transcarpathian Region (I), while in the Kiev area (II) sensitivity to insecticides varied insignificantly. Comparing insect resistance to widely used and new insecticides, it was found that sensitivity in (I) as against (II) was 30 fold lower for DDT, 15 fold for polychloropinene, 8 fold for dilor, and 3.5x for kelthane (dicofol). The results pointed to the acquisition of resistance in (I). Beetle populations in both areas were equally sensitive to organic phosphorus compounds (chlorophos, phthalophos, phosalone, cyanox).

158. Bouchard, M. (1983). Influences stationnelles sur l'alteration chimique des sols derives de till (Sherbrooke, Que., Canada). *CATENA* 10: 363-382.
Chem Codes: Chemical of Concern: PSM Rejection Code: FATE.

Summary In a small watershed of the canadian Appalachians, five trenches were studied in two catenas facing each other, one forested, the other under recent prairie vegetation (100 years of age), to investigate the character of chemical weathering in these sites. On the top of the forested catena there was a humo-ferric fragic podzol, and further down, and orthic gleysol. The other catena had a humo-ferric fragic podzol, then, downwards, a grey gleyified luvisol and a luvic fragic gleysol. Percolating waters near these trenches were sampled regularly, at various depth. The distribution of the ions on the meadow side indicated on one hand that H_4SiO_4, Na^+ and Mg^{2+} in percolating waters are related to the total volume of soil through wich waters percolate, that the dissolution of aluminium is accelerated in acid sites (upslope) and that the solubility of iron reaches a maximum in the zone influenced by the water table. On the other hand, calcium, which is easily liberated in the high sections, is in part fixed when the solutions get concentrated, iron and aluminium are soon traped, silicium is less mobile than the basic cations. The constituants of primary minerals organize as follows: concentration of Al_2O_3 and Fe_2O_3 upslope, when the contrary is for the basic oxydes and SiO_2; this trend stands out more clearly in the top 30 cm. Thus on top of the forested catena, chemical weathering is intense, the aluminium and iron oxydes

are highly evacuated in this podzol. At the same altitude, in the prairie podzol, which probaly had 100 years ago a less acidifying vegetation (hardwoods) than in the first case, feldspars and micas are degraded and we find mostly transformed minerals (montmorillonite -- Al). Minerals are very much less degraded downslope because of their confined position and the high ionic content of the percolating waters.Resume Dans un petit bassin-versant des Appalaches canadiennes, cinq fosses pedologiques ont ete etudiees dans deux catenas de part et d'autre de l'exutoire, l'une sous foret, l'autre sous prairie recente (la deforestation datant de 100 ans), afin de caracteriser l'alteration dans divers sites le long de la pente. La premiere catena comportait, de haut en bas du versant, un podzol humo-ferrique fragique, un luvisol gris gleyifie, un gleysol luvique fragique; la deuxieme, sous foret, un podzol humo-ferrique fragique, un gleysol orthique. Les eaux de percolation de ces profils ont ete prelevees regulierement, a diverses profondeurs ainsi que l'eau de l'exutoire. La distribution des ions dans la catena sous prairie a indique que d'une part les teneurs en H4SiO4, Na+ et Mg2+ sont liees au volume traverse, que l'aluminium est plus fortement mis en solution dans les sites acides (hauts de versants), que les teneurs en fer sont maximales dans les niveaux influences par le battement de la nappe phreatique. D'autre part, le calcium, fortement libere sur les hauteurs, se fixe en partie lorsque les solutions se concentrent, le fer et l'aluminium sont pieges tres tot alors que le silicium est moins mobile que les cations basiques. Les constitutants des mineraux primaires dans les sols s'organisent donc ainsi: concentration de Al2O3 et Fe2O3 vers le haut de versant, alors que c'est le contraire pour les oxydes basiques et SiO2, ce qui est plus evident dans les 30 cm de surface. Aussi, en haut de versant de coniferes l'alteration est intense, les sesquioxydes sont fortement evacues dans ce podzol, tandis qu'a la meme hauteur dans le podzol de prairie, qui portait il y a 100 ans sans doute une vegetation moins acidifiante (feuillus) que dans le premier, la degradation (des mineraux phylliteux et des feldspaths) et les transformations (en montmorillonite -- Al) predominent. La degradation des mineraux est faible dans les bas de versants par suite du confinement et de l'elevation des teneurs des percolats.

159. Boumaiza, M., Ktari, M. H., and Vitiello, P. ([Toxicity of Several Pesticides Used in Tunisia, for Aphanius Fasciatus Nardo, 1827 (Pisces, Cyprinodontidae.)]. *Arch inst pasteur tunis. 1979, sep; 56(3):307-42. [Archives de l'institut pasteur de tunis]: Arch Inst Pasteur Tunis*.
Chem Codes: Chemical of Concern: PSM Rejection Code: NON-ENGLISH.

ABSTRACT: The acute toxicity of some pesticides used in Tunisia is determined for the species Aphanius fasciatus (Pisces - Cyprinodontidae). Bioassays conducted at temperature (19-20 degrees C) and salinity (37-38%) have allowed to calculate the CL50 48 h and 96 h. The classification of these pesticides, based on the CL50 96 h, and according to their toxicity for the test species, shows that the organic phosphorus (Murphotox, Bazudin, Dursban, Zithiol, Lebaycid, Imidan, Oleoparathion, Folimat; Nuvan, Actellic, Carbicron, Nexion, Dimecron, Roxion) have all the degrees of toxicity, but the majority are among the most toxic; the carbamates (Betanal, Dimetilan, Baygon), are generally less toxic than the organic phosphorus tested, except Nexion which is less toxic than the Betanal and Roxion less toxic than the three carbamates tested; the herbicides (2,4-D, Basagran, Printan) have a very low toxicity, and are less toxic than the insecticides tested, except Betanal and Suffix of which the toxicity is higher than some insecticides (Nexion, Dimecron, Baygon, Dimetilan, Roxion); Calixin (Fongicide) is more toxic than the herbicides tested but it is generally less toxic than the insecticides used. At higher temperature (28-29 degrees C) A. fasciatus is more sensible to organic phosphorus (Dursban, Folimat) than to carbamate (Betanal). The variation change of salinity (from 37 to 6.5 %) don't modify the sensibility of the test species face to face of three pesticides: Dursban, Folimat (organic phosphorus insecticide) and Betanal (carbamate herbicide). A. fasciatus is suitable for acute and chronic bioassays.

CAS Registry Numbers: 732-11-6; 3735-33-9 Role: ANT (Analyte), ANST (Analytical study) (detn. of, in corn) A rapid quant. procedure is given for Imidan (O,O-di-Me S-phthalimidomethyl phosphorodithioate) and Imidoxon (O,O-di-Me S-phthalimidomethyl phosphorothioate), with min. detection levels of 0.002 and 0.004 ppm., resp. The compds., first sepd. on a silica-gel column, are individually gas chromatographed on a glass column contg. 10% DC-200 on 80-90 mesh Gas Chrom Q at 200 Deg. An important requirement is the conditioning of the column by repeated injections of insecticides to const. response. The flame photometric detector with a 526 mm interference filter (P detector) was not contaminated by unpurified exts. Index Terms: Milk (Imidan detn. in goat)
CAS Registry Numbers: 732-11-6 Role: ANT (Analyte), ANST (Analytical study) (detn. of, in milk) The high and low fat extn. procedures of B. and B. (ibid 49, 1007 (1966) for detg. insecticides in milk were applied to the detn. of the polar insecticide 0,0-di-Me S-phthalimidomethyl phosphorodithioate (Imidan) (I) as a contaminant in goats milk. The app. and gas chromatographic conditions are the same as those of B. and B. (CA 66: 45522a) for the analysis of I, except that a 394-mm filter is used with the flame photometric detector to detect the S rather than P in the mol. The limit of detection is 0.05 ppm. A 2.38-g. dose of I was given to a 34-kg. goat, and a milk sample was collected after 8 hrs.; I recoveries averaged 95 and 75% with the low and high fat extn. procedures, resp. The amts. of fat extd. by each procedure were 1.16 and 6.26 wt. %, resp. The amts. of I extd. by the 2 procedures were 0.36 and 0.25 ppm., resp. 2227-17-0 (Bi-2,4-cyclopentadien-1-yl, decachloro-); 2275-14-1 (Phosphorodithioic acid, S-[[(2,5-dichlorophenyl)thio]methyl] O,O-di-Et ester); 2437-33-4 (Benzenesulfonic acid, p-chlorophenyl ester); 2463-84-5 (Phosphorothioic acid, O-(2-chloro-4-nitrophenyl) O,O-di-Me ester); 2597-11-7 (4,7-Methanoinden-1-ol, 4,5,6,7,8,8-hexachloro-3a,4,7,7a-tetrahydro-); 2642-71-9 (Phosphorodithioic acid, O,O-diethyl ester S-ester with 3-(mercaptomethyl)-1,2,3-benzotriazin-4(3H)-one); 2667-49-4 (Phosphonothioic acid, methyl-, O-2,4-dichlorophenyl O-Me ester); 3369-52-6 (4,7-Methanoisobenzofuran, 4,5,6,7,8,8-hexachloro-1,3,3a,4,7,7a-hexahydro-); 3572-06-3 (2-Butanone, 4-(p-hydroxyphenyl)-, acetate); 3692-90-8 (Carbamic acid, methyl-, m-(2-propynyloxy)phenyl ester); 3737-22-2 (3,5-Pyridinedicarboxylic acid, diisopropyl ester); 5943-04-

4 (Sulfone, chloromethyl p-chlorophenyl); 6081-53-4 (2-Norbornene, 1,4,5,6,7,7-hexachloro-2-(dichloromethyl)-); 6119-92-2 (Crotonic acid, 2-(1-methylheptyl)-4,6-dinitrophenyl ester); 6369-96-6 (Acetic acid, (2,4,5-trichlorophenoxy)-, compd. with trimethylamine (1:1); 6734-84-5 (Ethane, 1,1,1-trichloro-2,2-bis(o-chlorophenyl)-); 7378-10-1 (2,5,7-Metheno-3H-cyclopenta[a]pentalen-3-one, 3b,4,5,6,6,6a-hexachlorodecahydro-); 12122-67-7 (Zinc, [ethylenebis[dithiocarbamato]]-); 18250-63-0 (Phosphoric acid, dimethyl ester, ester with cis-3-hydroxy-N,N-dimethylcrotonamide); 31116-84-4 (2-Propanone, (methoxyphenyl)-); 77287-19-5 (1,2,4-Methenocyclopenta[cd]pentalene-5-carboxaldehyde, 2,2a,3,3,4,7-hexachlorodecahydro-); 875253-22-8 (Crotonic acid, 3-hydroxy-, a-methylbenzyl ester) (detection of); 60-57-1 (1,4:5,8-Dimethanonaphthalene, 1,2,3,4,10,10-hexachloro-6,7-epoxy-1,4,4a,5,6,7,8,8a-octahydro-, endo-exo-) (detection of;); 72-20-8 (1,4:5,8-Dimethanonaphthalene, 1,2,3,4,10,10-hexachloro-6,7-epoxy-1,4,4a,5,6,7,8,8a-octahydro-, endo-endo-); 94-75-7 (Acetic acid, (2,4-dichlorophenoxy); 2104-64-5 (Phosphonothioic acid, phenyl-, O-ethyl O-p-nitrophenyl ester) (detection of; chromatog. of); 101-05-3P (s-Triazine, 2,4-dichloro-6-(o-chloroanilino)-) Role: PREP (Preparation) (extn. p-value of); 116-29-0 (Sulfone, p-chlorophenyl 2,4,5-trichlorophenyl) (partition of, p-value for); 70-38-2P (Cyclopropanecarboxylic acid, 2,2-dimethyl-3-(2-methylpropenyl)-, 2,4-dimethylbenzyl ester); 72-55-9P (Ethylene, 1,1-dichloro-2,2-bis(p-chlorophenyl)-); 80-33-1P (Benzenesulfonic acid, p-chloro-, p-chlorophenyl ester); 115-29-7P (6,9-Methano-2,4,3-benzodioxathiepin, 6,7,8,9,10,10-hexachloro-1,5,5a,6,9,9a-hexahydro-, 3-oxide); 12427-38-2P (Manganese, [ethylenebis[dithiocarbamato]]-) Role: PREP (Preparation) (prepn. of) cf. CA 62, 11087c. The extn. p-values (fraction of solute partitioning into upper phase of an equil. vol. 2-phase system) of 131 pesticides and related compds. in 6 solvent systems (hexane-acetonitrile, isooctane-dimethylformamide (DMF), isooctane-85% DMF, hexane-90% DMSO, heptane-90% EtOH, and isooctane-Me2CO) were detd. to aid in pesticide anal. and identification. The 85 compds. whose p-values were detd. by electron capture gas chromatog. have been tabulated in order of increasing retention time alongside their p-values to allow the best choice of the 6 solvent systems to be made for identification purposes. Remaining p-values were detd. gravimetrically. Math. formulas are given for calcg. from the p-values the fractional amt. extd. after repeated extns. Graphs are presented which allow the specificity of a given p-value in a given system to be detd. readily. [on SciFinder (R)] 0095-9111

P and S were detd. on packings contg. liq. phases OV-101, OV-17, OV-210, and OV-225, using a flame photometric detector. These packings have excellent thermal stability and are likely to find widespread use in pesticide residue anals., esp. for the identification of multicomponent residues in environmental samples or in samples of unknown or indefinite history. Relative retention times were detd. isothermally and by temp. programming; the latter procedure was more reproducible and more useful for analyzing mixts. with widely differing retention times. With temp. programming, it is possible to analyze compds. of widely differing volatiles in a single run with good sensitivity and a large saving in time. Compds. were detected with the flame photometric detector of Brody and Chaney in both the P- and S-sensing modes and were identified in milk and corn silage at levels as low as 0.01 ppm. Recoveries of the insecticides from corn silage exceeded 90% and more often were better than 95%; those from milk were at least 80% and usually were above 90%. The gas chromatog. in a single multicomponent anal. required from 12 to 28 min. The procedure shows promise for identification or multicomponent anal. of P- and S-contg. pesticides as well as for the monitoring of foodstuffs and forage for these pesticides. 32 references. 170. Brandt, Wolf F. and Frank, Gerhard (1988). Manual gas-phase isothiocyanate degradation. *Analytical Biochemistry* 168: 314-323.
Chem Codes: Chemical of Concern: PSM Rejection Code: CHEM METHODS.

We describe a manual gas-phase isothiocyanate degradation procedure for the primary structure determination of proteins and peptides. The proteins and peptides are applied to a polybrene-coated glass fiber filter wedged into a small glass column. The phenylisothiocyanate is directly pipetted onto the filter disk. The coupling and cleavage reactions are performed in small desiccators containing trimethylamine and trifluoroacetic acid vapors, respectively. The wash and extraction steps are performed by allowing the suitable solvents to percolate through the filter disk. The extracted anilinothiazolinone is then converted to the phenylthiohydantoin and identified by any one of a number of described methods. Our results show that this method is very sensitive and that the reactions proceed faster than those of the published automated procedure. No expensive equipment is required and the manual degradation can be performed by a laboratory assistant. A large number of samples can be simultaneously subjected to the degradation under identical conditions, making this an ideal method for physicochemical investigations into the isothiocyanate degradation. We also use this method to screen HPLC fractions after enzymatic protein fragmentation. Manually sequenced glass filters can be transferred to the automated instrument for more extended degradations. protein sequencing/ manual gas-phase/ isothiocyanate degradation http://www.sciencedirect.com/science/article/B6W9V-4DW2KF8-H3/2/0bbf8e7e44fbda60a3449c77944a0cc8

Of 25 pesticides that inhibited attachment, 23 (92%) were reported to be teratogenic in mammals or avians. From a qual. viewpoint, agents that inhibit attachment in vitro are very likely to be teratogenic in vivo. There was a quant. correlation between the inhibitory activity and the lowest reported teratogenic dose in chick embryo for 9 pesticides. However, no similar correlation between inhibitory concn., in vitro, and mammalian teratogenicity was found. Presumably maternal effects of absorption, metab., and distribution distort the relation between the dose administered to the mother and the concn. of teratogenic agent at target embryonic tissues. Lack of inhibition in vitro did not indicate lack of teratogenicity, as 5 or 8 noninhibitory agents were reported to be teratogenic in vivo. Such false negatives of the attachment assay may be detectable in complementary in vitro tests. [on SciFinder (R)] 0098-4108 pesticide/ teratogenicity

Citations: Whyatt, R; Environ Health Perspect 2001, 109, 417 Urinary dialkylphosphate (DAP) metabolites have been used to est. human exposure to organophosphorus pesticides. The authors developed a method for quantifying the six DAP urinary metabolites of at least 28 organophosphorus pesticides using lyophilization and chem. derivatization followed by anal. using isotope-diln. gas chromatog.-tandem mass spectrometry (GC-MS/MS). Urine samples were spiked with stable isotope analogs of the DAPs and the water was removed from the samples using a lyophilizer. The dried residue was dissolved in acetonitrile and di-Et ether, and the DAPs were chem. derivatized to their resp. chloropropyl phosphate esters. The chloropropyl phosphate esters were concd., and analyzed using GC-MS/MS. The limits of detection of the method were in the low mg/l (ppb) to mid pg/mL range (parts per trillion) with coeffs. of variation of 7-14%. The use of stable isotope analogs as internal stds. for each of these metabolites allows for sample-specific adjustment for recovery and thus permits a high degree of accuracy and precision. Use of this method with approx. 1100 urine samples collected from pregnant women and children indicate that the low limits of detection allow this method to be used in general population studies. An isotope-diln. gas chromatog.-tandem mass spectrometry (GC-MS-MS) method was developed for quantitating the six dialkyl phosphate urinary metabolites of at least 29 organophosphate pesticides. Urine samples were spiked with stable isotope analogs of the dialkyl phosphates, evapd. using azeotropic distn., followed by chem. derivatization of the metabolites to their resp. chloropropyl phosphate esters. The chloropropyl phosphate esters were concd. and then analyzed using GC-MS-MS. The limits of detection (LODs) of the method were in the low-to-mid picogram-per-milliliter range (parts per trillion) with coeffs. of variation of less than 20%. The use of stable isotope analogs as internal stds. for each of these metabolites allows for the highest degree of accuracy and precision. Addnl., the low LODs allow the use of this method in general population studies. (c) 2002 Preston Publications. Use of probability distributions to characterize exposure make it possible for (1) the continuum of data from the largest to the smallest values to be expressed, (2) the relative likelihood of occurrence to be described, (3) the uncertainty for each component to be reflected and for (4) the individual variability in the population to be captured. Exposure can be aggregated in a math. correct way and be characterized relative to benchmarks of toxicity such as the NOEL, the RfD, the ED10 or an upper bound cancer potency est. (Q1*). Using these procedures, the risk manager can det. the probability that exposure is less than or equal to an acceptable daily dose for the whole population or a selected subpopulation. 175. Breum, Niels O., Nielsen, Birgitte H., Nielsen, Eva M., Midtgaard, Uffe, and Poulsen, Otto M. (1997). DUSTINESS OF COMPOSTABLE WASTE: A METHODOLOGICAL APPROACH TO QUANTIFY THE POTENTIAL OF WASTE TO GENERATE AIRBORNE MICRO-ORGANISMS AND ENDOTOXIN. *Waste Management & Research* 15: 169-187.
Chem Codes: Chemical of Concern: PSM Rejection Code: FATE, BACTERIA.

The objective of the present study was to assess the effect of different waste storage systems on the potential of the waste to emit airborne dust, micro-organisms and endotoxin. Batches of 8.8 kg of compostable waste were incubated at 20[degree sign]C for periods of 1-2 weeks in three different storage systems: a system with relatively free access of air (FA) to the waste (paper bags in the kitchen, paper sacks outside the house), a system with low access (LA) of air (plastic bags in the kitchen, a container outside the house), and an intermediate (IA) system (trash can in the kitchen, a container outside the house). The compostable waste was prepared in the laboratory using a standard recipe simulating average kitchen waste in Denmark. Weight loss and temperature of the waste were recorded during the storage period. After incubation, the volume of percolate was determined and the dustiness of the waste was measured in terms of the potential of the waste to emit bio-aerosols in a rotating drum. Storage in the FA system resulted in high weight loss of the waste (15-25% per week), a maximum temperature of 45[degree sign]C and no percolate was observed. The LA system resulted in low weight loss (<3% per week), a temperature at ambient level and a volume of percolate less than 0.1 litre. Waste stored in the IA system was intermediate with a weight loss of 5-8% per week, a maximum temperature of 36[degree sign]C and a volume of percolate less than 1 litre. Dustiness in terms of dust, endotoxin and micro-organisms was highly correlated to weight loss of the waste. Storage of the waste in the FA system resulted in extremely high concentrations of airborne micro-organisms in the rotating drum compared to that seen after storage in the LA system. The dustiness with respect to airborneAspergillus fumigatuswas at least a factor of 400 000 higher for FA waste compared to LA waste. The present method of testing dustiness of waste is considered important for the design of waste collection equipment and may therefore, over time, contribute to an improved air quality for the workers engaged in waste handling. Dustiness; compostable waste; bio-aerosol; fungi; bacteria; endotoxin; weight loss; temperature; rotating drum tester; Denmark

Abstract: Lab and field investigations have been made of factors influencing the leaching of substances from beds of p.f.a. Results presented allow the likely pattern and quality of percolate from p.f.a. beds to be predicted. By combining these with hydrogeological data, a dumping regime can be specified so that risks will not arise to drinking, or other, water supplies.

Chem Codes: Chemical of Concern: PSM Rejection Code: SURVEY.

ABSTRACT: BIOSIS COPYRIGHT: BIOL ABS. One hundred sixty-two species were recorded as part of the arthropod community associated with peach in eastern West Virginia. The community was composed of 33% phytophages, 35% insectivores, 14% scavengers, and 18% tourists. Diversity of the arthropod community was correlated inversely with intensity of orchard management. Comparing the phytophagous community on apple (from an earlier study) with that on peach, Lepidoptera comprised 49% on apple and only 31% on peach; Hemiptera comprised 9% on apple and 19% on peach. Diversity of the phytophagous arthropod community was significantly less in peach than in apple orchards, but was more similar in commercially-managed orchards than in unmanaged orchards. It is concluded that in commercially-managed peach and apple orchards insecticide use is the dominant factor controlling community structure, whereas, in unmanaged orchards the communities in peach and apple evolve into distinctly different communities. ABSTRACT: The incineration of municipal solid waste (MSW) results in the annual production of 2.7 million tons of bottom ash in France. Utilisation of bottom ash in road construction is encouraged in France but strictly regulated. Because the incinerator residues contain enriched concentrations of metals and salts, particular attention must be focused on the potential environmental problems. In the present study, a laboratory tool (lysimeter) has been developed to reproduce the conditions of bottom ash utilisation and to study their environmental impact via the percolates collected at the bottom of the lysimeter. Four lysimeter experiments were conducted in order to study reproducibility, as well as the influence of water flow rate and pressure on the

composition of the percolates. The lysimeter experiments have been then compared with the utilisation of bottom ash under real conditions (two experimental road sections). The comparison of results of lysimeter test and those measured after performing the French standard leach test (AFNOR NF X31-210) shows a recovery of 89% for the chlorides and between 30 and 35% for the sulfates. This indicates that almost all chlorides have been dissolved, contrary to the sulfates, which are less soluble.

Of 35 compds. tested, 12 showed pos. results. Among those compds. detected by this method were azinphosmethyl [86-50-0], Bayrusil [13593-03-8], coumaphos [56-72-4], Dursban [2921-88-2], Imidan [732-11-6], and phosalone [2310-17-0]. Some pesticides which were not detectable by this method were diazinon [333-41-5], parathion [56-38-2], fenthion [55-38-9], and salithion [3811-49-2]. One approach to this method involves heating the coated plate prior to fluorometric anal., while the other involves spraying the plate with strong acid or base prior to heating. The limit of detection by this latter technique was 0.001 mg. ABSTRACT: PESTAB. This is a literature review which covers the broad area of the effects of pollution on freshwater fish. Specific areas covered in the literature survey include: reviews and symposia; water quality; pesticidal pollutants such as insecticides and other pesticides; industrial pollutants, including inorganics, and pulp and paper; domestic pollutants; and radioactive pollutants. Specifically mentioned under insecticide pollutants are DDE, DDT, dieldrin, chlorinated hydrocarbon pesticides, organophosphate and carbamate insecticides, chlordane, toxaphene, heptachlor, heptachlor epoxide, aldrin, mirex, piperonyl butoxide, methoxychlor, trifluralin, lindane, pyrethroids, methyl parathion, carbaryl, parathion, pentachlorophenol, arecoline, 2,4-D, enterobacterin, fenitrothion, dichlorvos, imidan, and malathion. Specific herbicides mentioned include diquat dibromide, potassium endothall, diquat, dinoseb, picloram, azoplant, benomyl, thiophanate-methyl, BCM, dalapon, fenuron, and folmar. Specific pesticides mentioned include rotenone, antimycin, and trifluoromethyl-4-nitrophenol (TFM).

Citations: Solomon, K; Crop Protection 2000, 19, 649 Assessment of risk posed by an environmental contaminant to an aquatic community requires estn. of both its magnitude of occurrence (exposure) and its ability to cause harm (effects). Our ability to est. effects is often hindered by limited toxicol. information. As a result, resource managers and environmental regulators are often faced with the need to extrapolate across taxonomic groups to protect the more sensitive members of the aquatic community. The goals of this effort were to (1) compile and organize an extensive body of acute toxicity data, (2) characterize the distribution of toxicant sensitivity across taxa and species, and (3) evaluate the utility of toxicity extrapolation methods based upon sensitivity relations among species and chems. Although the anal. encompassed a wide range of toxicants and species, pesticides and freshwater fish and invertebrates were emphasized as a reflection of available data. Although it is obviously desirable to have high-quality acute toxicity values for as many species as possible, the results of this effort allow for better use of available information for predicting the sensitivity of untested species to environmental contaminants. A software program entitled \"Ecol. Risk Anal.\" (ERA) was developed that predicts toxicity values for sensitive members of the aquatic community using species sensitivity distributions. Of several methods evaluated, the ERA program used with min. data sets comprising acute toxicity values for rainbow trout, bluegill, daphnia, and mysids provided the most satisfactory predictions with the least amt. of data. However, if predictions must be made using data for a single species, the most satisfactory results were obtained with extrapolation factors developed for rainbow trout (0.412), bluegill (0.331), or scud (0.041). Although many specific exceptions occur, our results also support the conventional wisdom that invertebrates are generally more sensitive to contaminants than fish are. The majority of OP pesticides can be classified structurally into four groups: phosphate, phosphorothiolate, phosphorothionate, and phosphorodithionate. The reaction of 3 OP pesticides, namely fenitrothion, quinalphos, and phosmet, is particularly described. 193. Butler, I. S. and Shaw, C. F. (1976). Vapor phase infrared spectrum and coriolis coupling constants of pentacarbonyl(thiocarbonyl)chromium(0). *Journal of Molecular Structure* 31: 359-365.
Chem Codes: Chemical of Concern: PSM Rejection Code: CHEM METHODS.

Several band contours have been successfully resolved in the high-resolution IR spectrum of pentacarbonyl(thiocarbonyl)chromium(0) vapor at ~312 K. However, PQR separations are only clearly discernible for the three v(CO) fundamentals (v1,v2 and v16). The good agreement between the observed and calculated PR separations of the two a1 v(CO) modes (v1 and v2) verifies the C4v prolate symmetrical top geometry of the molecule. From band shape analyses, the Coriolis coupling constants of the e v(CO) mode (v16) and the e [delta] (CrCO) mode (v17) are estimated to be --0.45 +/- 0.05 and --0.80 +/- 0.15, respectively.

ABSTRACT: PESTAB. Liquid emulsifiable concentrates of Trithion (carbophenothion) are diluted to an appropriate concentration with carbon disulfide and granular formulations and dusts are extracted with carbon disulfide-chlorform-acetone. The Trithion is then analyzed by flame ionization gas chromatography equipped with a 1.5 ft X 0.25 in. o.d. (0.16 in. i.d.) Pyrex glass column packed with 12% SE-30 on 80-100 mesh Gas Chrom Q. Imidan (phosmet) is used as an internal standard. Trithion residues are extracted with aqueous acetonitrile or hexane plus acetonitrile and cleaned up with alumina and Nuchar shakeouts. Trithion and three of the metabolites are then oxidized to the two sulfones, further cleaned up, and separated on a silica gel column. Determination is by gas chromatography using flame photometric detection in the phosphorus mode. The 900 mm X 2 mm i.d. acid-washed and silanized Pyrex column is packed with 10% OV-1 on 100-120 mesh Gas Chrom Q; a second column packed with 12% QF-1 on 100-120 mesh Gas Chrom Q may be used to confirm the identity of the thion sulfone or the oxon sulfone. The detection limit of the method is 0.002 ppm of the thion sulfone and 0.02 ppm of the oxon sulfone; recovery of the thion sulfone ranges from 80 to 100% and recovery of the oxon sulfone ranges from 90 to 120% from fruits and dry beans and from 70 to 90% from oily mataerial.

ABSTRACT: PESTAB. Prefar (bensulide) in formulation samples is determined by gas chromatography with Imidan as internal standard. Liquid emulsifiable concentrates are first diluted with carbon disulfide, while granular formulations and dusts are extracted with carbon disulfide-chloroform-acetone. The recommended instruments is a Hewlett-Packard Model 402 equipped with a hydrogen flame ionization detector and a 1.5 ft X 0.25 in. o.d. Pyrex glass column packed with 3% OV-1 on 60-80 mesh Gas Chrom Q. Off-column injection without an elevated inlet temperature is suggested. Prefar residues in macerated crop samples and water are extracted with benzene, while soil samples are shaken with methanol-water, then with benzene and aqueous solution chloride solution. When required, cleanup may be by Nuchar shakeout, solvent partition, or liquid column chromatography. Analysis is by gas chromatogrphy on a Varian-Aerograph Model 600D equipped with an alkali flame ionization detector and a 300 X 2 mm i.d. Pyrex glass column packed with 10% DC-200 silicone oil on 100-120 mesh Gas Chrom Q. The limit of detection is 0.05 ppm, recoveries generally range from 90 to 105%, and none of the registered phosphorus-containing pesticides have the same retention time as Prefar or its oxygen analog.

197. Byrem, William C., Armstead, Stephen C., Kobayashi, Shunji, Eckenhoff, Roderic G., and Eckmann, David M. (2006). A guest molecule-host cavity fitting algorithm to mine PDB for small molecule targets. *Biochimica et Biophysica Acta (BBA) - Proteins & Proteomics* 1764: 1320-1324.
Chem Codes: Chemical of Concern: PSM Rejection Code: CHEM METHODS.

Inhaled anesthetic molecule occupancy of a protein internal cavity depends in part on the volumes of the guest molecule and the host site. Current algorithms to determine volume and surface area of cavities in proteins whose structures have been determined and cataloged make no allowance for shape or small degrees of shape adjustment to accommodate a guest. We developed an algorithm to determine spheroid dimensions matching cavity volume and surface area and applied it to screen the cavities of 6,658 nonredundant structures stored in the Protein Data Bank (PDB) for potential targets of halothane (2-bromo-2-chloro-1,1,1-trifluoroethane). Our algorithm determined sizes of prolate and oblate spheroids matching dimensions of each cavity found. If those spheroids could accommodate halothane (radius 2.91 A) as a guest, we determined the packing coefficient. 394,766 total cavities were identified. Of 58,681 cavities satisfying the fit criteria for halothane, 11,902 cavities had packing coefficients in the range of 0.46-0.64. This represents 20.3% of cavities large enough to hold halothane, 3.0% of all cavities processed, and found in 2,432 protein structures. Our algorithm incorporates shape dependence to screen guest-host relationships for potential small molecule occupancy of protein cavities. Proteins with large numbers of such cavities are more likely to be functionally altered by halothane. Citations: Sorensen, S; Pan-Pac Entomol 1996, 72, 160 The glassy-winged sharpshooter Homalodisca coagulata Say (Homoptera: Cicadellidae) is a new pest to California agriculture. It is the principal vector of several plant pathogenic diseases, particularly Pierce's Disease in grapevines, and oleander leaf scorch. A microplate-based assay is described that measures the sensitivity of acetylcholinesterase (AChE) activity to inhibition by organophosphorus (OP) insecticides in this important pest. The technique provides users with an accurate measure of the efficacy of OP binding to this target site, and is a valuable tool for monitoring field populations of the insect to det. whether the use of OP insecticides has selected for resistant individuals. The technique will also measure AChE sensitivity in the smoke-tree sharpshooter, H. lacerta Fowler. This species is native to California and is regarded only as a minor pest. Both inhibition and kinetic measurements for the AChE enzymes in these sharpshooters demonstrate the close phylogenetic relationships between the two species. [on SciFinder (R)] 0022-0493

200. Cabanillas, C. G. and Bushway, R. (1991). Analysis of Phosmet and Azinphos-Methyl in Apples by High-Performance Liquid Chromatography. *J liq chromatogr* 14: 3603-3614.
Chem Codes: Chemical of Concern: PSM Rejection Code: CHEM METHODS.

ABSTRACT: BIOSIS COPYRIGHT: BIOL ABS. A high-performance liquid chromatography (HPLC) method has been developed to analyze two organophosphate insecticides (phosmet and azinphosmethyl) in apples. The procedure includes a novel extraction whereby whole apples are sonicated for 2 min in 100 mL of MeOH to remove the pesticides. Reversed-phase HPLC separation was accomplished with an Ultremax C18 column and acetonitrile:methanol:water as the eluent. Detection was at 224 nm for phosmet and 300 nm for azinophos-methyl. For both pesticides the limit of detection was 0.5 ppb and the linearity was from 1 to 405 ng injected. Average recoveries were 80% for phosmet and 86% for azinphos-methyl. Thirteen apple varieties comprising 240 apples were analyzed from supermarkets and roadside stands for phosmet (amount found ranged from none detected tp 1244 ppb) and azinphos-methyl (amoung found ranged from none detected to 388 ppb). Confirmation of phosmet and azinphos-methyl was made by UV spectral scans.

The spectra produced during the elution profile of various pesticides via capillary gas-chromatog. introduction have indicated a large percentage of an electron ionization (EI) spectral component superimposed on the CI spectrum. This duplicity of several character can be an important asset for confirmation of presence and it does not present a problem of obtaining acceptable precision and accuracy on quantification of pesticide residues. The precision and accuracy of the anal. approach was ?15% relative std. deviation. A comparison study of >100 incurred residues analyzed by the ion trap and gas chromatog. with an array of element-selective detectors indicated that sample clean-up will probably be necessary before quantification is acceptable for all target compds. The data obtained using a combination of gas chromatog. and mass spectrometry and presented for 250 target pesticides constitutes the basic information required to duplicate and extend the methodol. 205. Callanan, Michael J., O'Toole, Paul W., Lubbers, Mark W., and Polzin, Kayla M. (2001). Examination of lactococcal bacteriophage c2 DNA replication using two-dimensional agarose gel electrophoresis. *Gene* 278: 101-106.
<u>Chem Codes</u>: Chemical of Concern: PSM <u>Rejection Code</u>: VIRUS.

The ori locus of the prolate-headed lactococcal bacteriophage c2 supports plasmid replication in Lactococcus lactis in the absence of phage infection. To determine whether phage c2 DNA replication is initiated at the ori locus in vivo and to investigate the mechanism of phage DNA replication, replicating intermediates of phage c2 were analyzed using neutral/neutral two-dimensional agarose gel electrophoresis (2D). The 2D data revealed that c2 replicates via a theta

mechanism and localized the initiation of theta replication to the ori region of the c2 genome.

ABSTRACT: BIOSIS COPYRIGHT: BIOL ABS. Supercritical fluid extraction (SFE) has become a promising alternative technique in the recent years for solid and semi-solid matrices, due to its advantages over classical solvent extraction (especially Soxhlet extraction). This paper briefly presents the strategy for the development of an SFE method, before reviewing the main results concerning pesticides and their metabolites in different matrices.

209. Campbell, G. S. (1986). Extinction coefficients for radiation in plant canopies calculated using an ellipsoidal inclination angle distribution. *Agricultural and Forest Meteorology* 36: 317-321.
Chem Codes: Chemical of Concern: PSM Rejection Code: MODELING.

Equations used to calculate extinction coefficients for radiation in plant canopies tend either to be too simple to describe canopy radiation accurately, or too complex for convenient computation. An equation has been derived using the assumption that the angular distribution of leaf area in a canopy is similar to the distribution of area on the surface of a prolate or oblate spheroid. This is therefore a generalization of the spherical leaf angle distribution which is frequently used for plant canopies. Simulated leaf angle distributions generated using this model closely approximate measured leaf angle distributions for plant canopies. Extinction coefficients calculated from the model give values which are virtually identical to those calculated using six leaf angle classes.

Patent Application Country: Application: WO
Priority Application Country: US
Priority Application Number: 2000-483084
Priority Application Date: 20000114 The present invention provides non-aq. compns. which comprise a pharmacol. or biol. active compd., an emulsifier, a polyol, and benzyl alc. The compns. are useful for administering the pharmacol. or biol. active compds. which they contain to animals, plants, or ground surfaces. In preferred embodiments, the pharmacol. or biol. active compds. may be water-insol. or water-labile. The compns. of the present invention allow these compds. to be solubilized and conveniently transported to a site of application in a non-aq. form, and then dild. in an aq. soln. In a particularly preferred embodiment, the compd. is ivermectin and is administered in the drinking water of poultry. The compns. of the present invention may also contain multiple pharmacol. or biol. active compds. which are administrated simultaneously. The present invention also provides methods of administering the compds. In the most preferred embodiment, the compds. may be administered in the drinking water of animals to be treated with the pharmacol. or biol. active compd. In other embodiments, the compns. may be topically applied to the animals or plants to be treated, or sprayed onto plants, animals, or a ground surface to be treated with the active compds. A nonaq. formulation of ivermectin was prepd. and dild. into the drinking water of male turkeys. The formulation was effective in completely eliminating any visible signs of roundworm infestation. ABSTRACT: BIOSIS COPYRIGHT: BIOL ABS. A systematic collection of throughfall (rain passing through the canopies), stemflow (rain flowing over the stems), and soil percolates was carried out in a Acacia dealbata plantation during one year, and its allelopathic capacity was biotested using Lactuca sativa L. var. Great Lakes. The results showed an allelopathic effect related to flowers: Germination of L. sativa was inhibited 30% by throughfall, 60% by stemflow, and 75% by soil percolates during the blossoming of A. dealbata, while radicle growth of L. sativa was inhibited 23%, 33%, and 48% by the same solutions. Climatic factors, particularly rainfall some days before, were also important. The three types of samples showed significant toxicities during some periods of the year, particularly percolates, which retained toxicity for a longer time, due perhaps to the decomposition of flowers fallen on the around.

Abstract: Acetolysed pollen from 66 of 74 species of Strobilanthes Blume from southern India and Sri Lanka were examined using light and scanning electron microscopy. Pollen descriptions, scanning electron micrographs, and a key are provided. Two shape classes have been distinguished, spheroidal and ellipsoid (prolate /subprolate). All ellipsoid pollen grains are tricolporate and have pseudocolpi. Six ellipsoid pollen types have been recognised based primarily on differences in rectal ornamentation. Sixteen spheroidal pollen types have been recognised based on variation in number, distribution and form of apertures, and on sexine structure. The current study has shown that variation in pollen morphology is much greater than was previously described, and that the pollen morphology of many species was incorrectly described by Bremekamp (1944). Bremekamp split Strobilanthes s.l. into 54 genera, and made extensive use of pollen morphological characters for generic delimitation. The results of the current study highlight fundamental problems with Bremekamp's classification and demonstrate the necessity of very extensive sampling and rigorous empirical investigations to resolve problems of generic delimitation in large, species rich groups.

It is disclosed that exptl. well-characterized compds. may serve as substitutes for highly toxic compds. in exptl. studies without exhibiting the same extreme toxicity, while from an overall viewpoint they exhibit analogous environmental characteristics. Citations: Verhaar, H; Quant Struct-Act Relat 1994, 13, 133 Organophosphates, esp. the so-called nerve agents including G-agent like Sarin, Tabun, Soman, and V-agents like VX are in general highly toxic substances. Data on the latter compds. are typically classified material and thus only scarcely available. However, a wide variety of structurally related compds. are well known and well characterized, i.e., organophosphor insecticides. Partial order ranking appears as an obvious possibility to remedy the lack of availability of data. Through the partial ordering it is possible to give the nerve agents an identity by comparing them to structurally related organophosphor insecticides and hereby obtain data necessary in order to perform a risk assessment in relation to the demilitarization activities. The paper describes the development of a partial order based ranking of Organophosphates with focus on selected nerve agents. Descriptors applied to rank these substances are \"noise-deficient\" QSAR generated data, i.e., data not being hampered by random fluctuations as they are forced to obey a first order equation. Potential substitutes for nerve agents to be applied in, e.g., exptl. studies are disclosed based on an anal. of av. ranks. [on SciFinder (R)] 0340-6253 organophosphate/ insecticide/ nerve/ agent

Citations: 20) Walker, J; SAR QSAR Environ Res 2002, 13, 713 Nerve agents like Sarin, Tabun, Soman, VX, Amiton etc. are highly toxic organophosphates (OPs) that exert their toxic effect by inhibition of acetylcholine esterase. These compds. have received considerable interest due their

inherent nature as weapons of mass destruction. Since these compds. have been developed for military purposes, data is typically classified material and thus only scarcely available. QSAR modeling is an obvious possibility in order to remedy the lack of data availability. However, a wide variety of structurally related OP insecticides are well known and well characterized. \"Noise-deficient\" QSARs, i.e., a QSAR model where the natural variation in both the exptl. data and the primary models data has been suppressed in a subsequent modeling step, for physicochem. properties of nerve agents are based on the use of the EPI Suite, a general QSAR model from the US EPA. Partial order ranking is an important tool to establish an identity for nerve agents relative to well-known OP insecticides. The development of a simple QSAR model for toxicol. properties was unsuccessful. The results described in the paper are obtained using QSAR modeling based on the EPI Suite in comparison with partial order ranking. The concept of \"noise deficient\" QSARs is introduced. \"Noise deficient\" QSARs can be obtained using EPI Suite generated data in combination with exptl. data for the test set, the data subsequently being applied in the ranking exercise. In the present study it is shown that to a certain extent selected insecticides may act as substitutes for nerve agents in preliminary exptl. studies. The paper suggests that exptl. well-characterized compds. may be selected as substitutes for highly toxic compds. for preliminary exptl. studies of the environmental behavior of the latter. Citations: Zar, J; Biostatistical Analysis 1999 The implementation of eco-toxicol. assessment in South America is presently limited due to significant scientific information gaps concerning native species and their potential use as biomarkers. Recently, a common southern hemisphere fish species, Astyanax fasciatus, has been pointed out as a potential bio-indicator to anthropogenic pollution. This is a small, abundant, Neotropical characid, which is widely distributed from

Central America south, to the Rio de la Plata Basin of western Uruguay. Our study found a statistically significant increase of coproporphyrin, uroporphyrin and protoporphyrin concns. in hepatic tissues of A. fasciatus collected from a stream segment with high anthropogenic disturbance (due mainly to agricultural derivs. and motor vehicle transportation activities). Although the area studied showed differences in up and downstream limno-chem. parameters, these differences were not related to the increase of hepatic porphyrin concns. We conclude that A. fasciatus is a good bio-indicator of exposure to environmental contaminants, and we propose that this abundant fish species be considered as a sentinel organism for monitoring potential disturbances to freshwater ecosystems. ISSN: 0024-4201
Abstract: Ester waxes and steryl glycosides of the grass Festuca argentina were studied. Saponification of the waxes from the petroleum ether extract led to n-hexacosanol as the major single linear alcohol, along with pentacyclic triterpenols, such as beta -amyrin, germanicol, isobaurenol, lupeol, hopenol-a and hopeol, and low amounts of sterols, such as cholesterol, campesterol, stigmasterol, sitosterol and dihydrositosterol, identified by gas chromatography/mass spectrometry (GC/MS). Fatty acids were identified as methyl esters as C(12:0), C(14:0), C(16:0), C(18:0), C(18:2), and C(20:0). The occurrence of a wide chainlength range of fatty acids and a single linear alcohol closely matched for other reports on the tribe Festuceae. On the contrary, pentacyclic triterpenols with a variety of skeletons, especially isobauerenol, are not usual as esters of fatty acids in the Gramineae. Low amounts of steryl glycosides were also obtained from the methylene chloride percolate of the methanol extract. Upon acetylation followed by hydrolysis, aglycones were identified by capillary gas-liquid chromatography (GLC) and GC/MS. As Delta superior 7-cholesterol, campesterol, stigmasterol, sitosterol, dihydrositosterol, and the sugars and glucose, xylose, and arabinose by GLC of the respective alditol acetates. This is the first report on the linear, steryl, and triterpenyl esters of F. argentina. It is noteworthy that Delta superior 7-steryl glycosides are rare, and steryl monoarabinosides have not been previously reported on the family Gramineae.

While there are other fragment-based modeling routes, our approach exploits the possibility of prioritizing fragments' contributions to toxicity. On the assumption that one fragment might be mainly responsible for the mol. toxicity, we developed a three-stage modeling strategy to select the most important moieties and to establish their priorities at a mol. level. This strategy was tested on a heterogeneous dataset contg. 282 pesticides, collected under the EU-funded project Demetra. Quant. toxicity prediction yielded good results for the training set (R2TR = 0.85) and the test set (R2TS = 0.75). The advantages and limitations of the current priority strategy are examd. Chem Codes: Chemical of Concern: PSM Rejection Code: IN VITRO.

A panel of monoclonal antibodies was raised against late yolk sacs of the stick insect Carausius morosus and tested by immunoblotting to establish the extent vitellin polypeptides are processed proteolytically during embryonic development. Cryosections of late yolk sacs were also examined by confocal laser microscopy to determine how vitellin cleavage products become spatially distributed amongst yolk granules during the same developmental period. Distinct labelling patterns were obtained on yolk granules depending on: (1) the nature of the proteolytic processing; (2) the origin of vitellin cleavage products; and ultimately (3) their molecular sizes. Monoclonal antibodies raised against vitellin cleavage products resulting from proteolytic processing appeared to label: (1) the entire volume of many yolk granules; (2) their limiting membrane; or (3) a number of small vesicles interposed between larger yolk granules. On the other hand, monoclonal antibodies against vitellin cleavage products that remain invariant throughout development appeared to label either the serosa membrane or the cytosolic space comprised between adjacent yolk granules. Data are interpreted as indicating that vitellin cleavage products may leak out from the yolk granules, gain access to the cytosolic space of the vitellophages and eventually percolate through the serosa membrane enclosing the yolk sac. Language: written in English. An area of insecticide exposure assessment which has received little attention in the past is that of exposure resulting from contact with pets who have been treated with insecticidal flea control products. It is possible that some of these residential exposures may be appreciable, esp. shortly after application of the insecticide. Our labs. are currently involved in

expts. to quantitate the dislodgeable residues from organophosphate flea dips or flea collars. The residues are obtained by rubbing the backs of dogs with white cotton gloves, followed by extn. and gas chromatog. Both chlorpyrifos and phosmet dips yielded high initial residues which dissipated quickly. The tetrachlorvinphos collar yielded slowly dissipating residues. At present, a chlorpyrifos collar is being tested, including monitoring of urinary metabolites in a child and an adult in the household of the dog. IACUC and IRB approvals were not difficult to obtain. Recruitment and compliance of the first three dog-only studies was relatively easy, whereas recruitment of households for the last study involving biomonitoring has been considerably more challenging. Two factors contributing to this challenge are the more limited group of households available (requiring a child in the 4-12 yr of age range) and the concern of some parents for the possible adverse effects of the insecticide on the child. 225. Chan, Hak-Kim and Gonda, Igor (1989). Aerodynamic properties of elongated particles of cromoglycic acid. *Journal of Aerosol Science* 20: 157-168.
Chem Codes: Chemical of Concern: PSM Rejection Code: CHEM METHODS.

Crystals of cromoglycic acid were prepared by precipitation and recrystallization from water. Aerosols of dry CA particles in air were generated by nebulizing a dilute suspension of CA and drying. The aerodynamic properties of these particles were measured directly by cascade impaction which gave a mass median aerodynamic diameter MMAD = 0.7 [mu]m and geometric standard deviation [sigma][sigma] = 1.9. The aerodynamic diameters were also calculated from the geometric dimensions obtained from electronmicrographs with, or without, the shadowing technique for determination of the thickness of the particles. Two methods derived for the aerodynamic behaviour of prolate spheroids and an empirical equation for elongated particles (Johnson, J. Aerosol Sci. 17, 426-430, 1986; Johnson et al., J. Aerosol Sci. 18, 87-97, 1987) were employed. The calculated MMAD and [sigma][sigma] assuming perpendicular orientation of the elongated particles with respect to the direction of motion were in reasonable agreement with the values obtained by cascade impaction. http://www.sciencedirect.com/science/article/B6V6B-48C8MM4-J/2/5a63cdf020e658d475008387b11289bb

Chem Codes: Chemical of Concern: PSM Rejection Code: CHEM METHODS.

The theory of diffusion charging of aerosol particles by unipolar ions having no external electric fields, is re-examined for arbitrary particle shape. For smaller effective Knudsen number (continuum limit), the time history of the charging of arbitrarily shaped particles can be obtained when the capacitance of the particles is known. For larger effective Knudsen numbers, the time history of the charging of arbitrarily shaped particles can be obtained when the capacitance and surface area of particles are known. Systematical analyses have been presented for bipolar sphere, oblate and prolate spheroids. The effect of gravitational motion of large aerosol particles on the charging process has been discussed. http://www.sciencedirect.com/science/article/B6V6B-48BDP55-1Y/2/86f36a7cbdfb95c5f9c7797d32abe92b

Chem Codes: Chemical of Concern: PSM Rejection Code: CHEM METHODS.

Numerical and experimental simulations have been conducted for the time history of the diffusion charging process on the surface of aerosol particles by dense bipolar ions under continuum conditions. The range of conditions treated in the numerical simulations include positive-negative ion diffusion coefficient ratio from 0 to 1, aerosol particle radius from 0.1 to 10 [mu]m, Debye ratio Rp/[lambda]D from 0 to 1 (equivalent to maximum charge density up to N1 = 1012 cm-3 for an ion temperature of 300 K), the major-to minor axis ratios of prolate spheroids, L, from 1 to 100. The experimental simulation was conducted by using a conductive dummy particle suspended by a thin shielded wire, and the charged particle deposition current flux was measured and the bipolar environments. Then the effect of particle surface charges was simulated by imposing an electric potential on the dummy particles. The results show that, (1) for small ion density (Rp/[lambda]D [less-than-or-equals, slant] 10-2); the present results are in good agreement with model of Chang et al. (1978, 1983). (2) the aeroso particle charging speed and charging limit increase with increasing Debye ratio; (3) for larger Debye ratio, bipolar charging is faster than unipolar charging; (4) the effect of particle shape L is observed to be significantly influenced by Debye ratios: (5) the charging limit of the aerosol particle increases with L. http://www.sciencedirect.com/science/article/B6V6B-4888DFM-3K/2/65ba0b0cdceb81db12ce470a461de03d

Citations: 31) Budavari, S; The Merck index 11th ed 1989 The objectives of this study are:. (1) To collect and analyze the data of pesticide residues in vegetables and fruits in central Taiwan;. (2) To compare the statistics of pesticide residues data in vegetables and fruits in 4 regions of Taiwan; and. (3) To introduce the Hazard Anal. Crit. Control Point (HACCP) system to industries and growers of vegetables and fruits for improving the safety of agricultural products. The 1999 samples of vegetables and fruits were collected from supermarkets and traditional markets by 6 local bureau of health in central Taiwan (1999-2004) and analyzed for the presence of 70.apprx.79 pesticide residues using multiresidue anal. methods (MRMs). The detection limits of these methods ranged from 0.03 to 0.4 ppm. For central Taiwan (1999-2004), pesticide residues were either absent or compliant with the Maximum Residue Limit (MRL) in 99.8% of the samples. Only 4 samples contained a pesticide residue that exceeded the MRL (0.2%, 4 of 1999). In whole Taiwan (1997-2003), pesticide residues were detected in 13.9% of the 9955 samples and 1.2% were violative. To decrease the health risk to human and environment from exposure to pesticides, the government samples and analyzes agricultural products for pesticide residues to enforce the limits set by Department of Health every year. Risk assessment and HACCP have some overlapping components; both HACCP and risk assessment are encompassed in risk anal. HACCP is a preventative system and will provide a high level of food safety assurance. However, effective HACCP requires the consideration of all hazards, i.e. chem. (food additives, heavy metal contamination, pesticide residues, and animal drug residues), microbiol. and phys. hazards. HACCP principles have been incorporated into food safety legislation in Taiwan and worldwide. [on SciFinder (R)] 1021-9498 pesticide/ residue/ risk/ assessment/ vegetable/ fruit

Samples from 205 rain events collected at 8 sampling stations in 1997-1998 were analyzed for pesticide residues of which 186 events (90%) yielded at least 1 pos. detection. Among 160 target pesticides and some major conversion products recovered by solid-phase extn. and analyzed by gas chromatog.-ion trap mass spectroscopy, 47 compds. were obsd. in at least 1 rain event. The most frequently obsd. pesticides were alachlor (49%), lindane (44%), parathion-Me (38%), atrazine (30%), quintozene (28%), metolachlor (24%), prometryne (23%), and molinate (22%). Diazinon, chlorpyrifos-Et, methidathion, ethofumesate, and parathion occurrence accounted for 14-17% of analyzed samples. The remaining target analytes were present in <10% of analyzed samples. Concns. of individual compds. were 0.002-6.82 mg/L. Greater pesticide concns. occurred in application seasons. Estd. annual deposition rates for the sum of pesticides were 51-395 mg/m2 of soil surface. Chem Codes: Chemical of Concern: PSM Rejection Code: CHEM METHODS.

ABSTRACT: BIOSIS COPYRIGHT: BIOL ABS. A systematic method for determination of 42 kinds of pesticides (organophosphorus, organonitrogen and pyrethroid pesticide) in citrus fruits was developed. The pesticides were extracted from the citrus fruits with acetone, and the extract was concentrated. After addition of ethyl acetate to the concentrated solution, both acid and basic compounds were removed. The ethyl acetate layer was then subjected to capillary GC with NPD detection after clean-up with a Sep-pak Florisil cartridge. The recoveries of 42 pesticides added to lemon at 0.010etection limits were 0.01 0.2 mug/g.

Chem Codes: Chemical of Concern: PSM Rejection Code: NON-ENGLISH.

ABSTRACT: Experiments were conducted on rats; in depression of blood cholinesterase activity by 68.6 percent phthalafos proved to decrease the myocardial nicotinamide coenzymes content on account of reduction in the amount of the oxidized forms. In the liver phthalafos diminished the content of oxidized and reduced forms of nicotinamide coenzymes, decreased the level of adenylic nucleotides chiefly at the expense of ATP. Diproxim prevented the changes caused by phthalafos in blood cholinesterase reactivation to 47.5 percent. It is supposed that the capacity of diproxim to normalize the oxidative processes in the cell by acting upon the nicotinamide coenzymes and adenylic nucleotides underlies its antidote action.

ABSTRACT: PESTAB. The influence of dipyroxime on the content of nicotinamide coenzymes and adenylic nucleotides in the myocardium and liver of rats poisoned with phthalophos was studied. The concentration of 68.8% phthalophos decreased the myocardial nicotinamide coenzymes content due to a reduction in the amount of the oxidized forms. In the liver phthalophos diminished the content of oxidized and reduced forms of nicotinamide coenzymes, decreasing the level of adenylic nucleotides chiefly at the expense of ATP. Dipyroxime prevented the changes caused by phthalophos in blood cholinesterase reactivation to the extent of 47.5%. It is suggested that the capacity of dipyroxime to normalize the oxidative processes in the cell by acting on the nicotinamide coenzymes and adenylic nucleotides underlies its antidote action.

ISSN: 0378-3774
Descriptors: Shrink/swell soil
Descriptors: Microsprinkler
Descriptors: Preferential flow

Abstract: Preferential flow allows agricultural chemicals to rapidly move past crop root zone to subsoil, potentially contaminating groundwater. Deep shrinkage cracks in a shrink/swell soil may serve as preferential flow channels. Design and operation of an irrigation system is critical in shrink/swell soils in order to reduce or eliminate preferential flow while providing sufficient water for plant growth. The objective of this study was to compare microsprinkler irrigation (MI) and surface flood irrigation (FI) systems for their ability to reduce preferential flow and chemical leaching through a shrink/swell soil in a pear orchard. The MI system applied water at a rate of 2.8 mm h⁻¹, and the FI followed the traditional orchard irrigation method. Bromide tracer was applied to the pear orchard. Soil cores and percolate samples from passive capillary samplers (PCAPS) installed at 1.2 m depth were collected to test for the presence of Br tracer in the soil and percolate. The MI system greatly decreased water and Br leaching from soil to the PCAPS in comparison to FI. The percolate in MI was nearly zero. Most of the loss of Br occurred in the first one or two FI events. MI systems, such as that used in this study should be considered as an alternative to FI in such shrink /swell soils to reduce macropore flow. (copyright) 2002 Elsevier Science B.V. (Acephate); 51712-33-5 (Po-226) Role: BIOL (Biological study) (in Chinese diet) The Chinese total diet study in 1990 estd. the dietary intake of 24 chem. contaminants and 72 nutrients from 4 market baskets collected and prepd. in 12 provinces. Twelve food group composites were made for each regional market basket. The overall dietary Pb, Cd, Hg, hexachlorocyclohexane HCH, and DDT intakes were well below their corresponding acceptable daily intakes. However, the Pb content of eggs from the 2 southern regions exceeded the tolerance limit. The Hg content of legumes just reached the tolerance limit, and Hg in eggs from the North 1 region exceeded the tolerance limit. The dietary HCH intake has increased significantly since the 1980s, but dietary DDT intake has decreased rather slowly. Five organophosphorus pesticides were detected out of a total of 12 organophosphorus pesticides analyzed. Among them, methamidophos was the most outstanding. The intake of total committed dose equiv. (CDEs) of the 6 radionuclides was 0.24 mSv/a; only 1.5% was accounted for by 90Sr and 137Cs. 210Pb, 210Po, 226Ra, and 228Ra accounted for 98.5% of the total CDEs. The main food sources of those radionuclides were cereals, vegetables, and aquatic foods. Aflatoxin B1 was detected at very low levels only in the cereal composite of the North 1 region. Aflatoxin M1 was not detected in any of the milk and milk products. The overall results show that there is no significant environmental contamination of the av. Chinese diet. Descriptors: TEM
Descriptors: Phylogenetic
Descriptors: Taxonomy
Abstract: Smilacaceae are a small family of dioecious, mostly climbing, net-veined monocotyledons with a cosmopolitan distribution. Relatively little is known about the variation of pollen morphology within the family. For this reason, and to investigate the systematic value of palynology in Smilacaceae, pollen from 125 species of Smilax, Heterosmilax, and Ripogonum was examined using light and scanning electron microscopy. Ten of these were examined further by transmission electron microscopy. Four distinct pollen types grouped into two major pollen classes were distinguished: Class 1, represented by the pollen of all Smilax and Heterosmilax species, is mostly spheroidal, inaperturate, and spinulate or microspinulate, with a thin, fragile exine of varied sculpturing; three pollen types are represented within this class. Class 2 is found only in Ripogonum and contains a single pollen type with prolate, monosulcate, reticulately-sculptured pollen. The unique pollen morphology of Ripogonum supports its removal from Smilacaceae. In contrast, the characteristics of Heterosmilax pollen intergrade with those seen in Smilax, suggesting that the former might be better reduced to synonymy with the latter. A key to the identification of these pollen types is presented along with a discussion of geographic and possible evolutionary trends among them. (copyright) Springer-Verlag 2006.

The rate consts. ranged from 265.2 +- 12.8 10-7 s-1 (Dichlorvos [62-73-7], 0.67 mg/cm2) to 9.3 +- 1.2 * 10-7 s-1 (p,p--DDE [72-55-9], 0.67 mg/cm2). The rate consts. began to decrease when the concn. of the pesticides on glass plates reached a certain concn. level. The mechanism for the variation of the rate const. is discussed from the viewpoint of the thickness of the pesticide mol. layer on the plates. There were no significant relationships between the extinction coeffs. in the 295-305 nm wavelength range and the photodegrdn. rate for the various pesticides. Descriptors: Ellipsoid of revolution
Descriptors: Experimental modal analysis
Descriptors: Finite element analysis
Abstract: This article presents modeling and experimental analyses on the vibrations of agricultural products of ellipsoidal shape, such as watermelon and cantaloupe. Since watermelon is solid while cantaloupe is hollow, different vibration characteristics are expected. Finite element (FE) models of watermelon and cantaloupe were first generated based on measured geometry: It was found that their mode shapes resemble those of spherical models. Comparisons of FE and experimental modal parameters show that both results agree well in mode shapes as well as natural frequencies. A significant difference between the two types of melons is the order of modes. The first mode of watermelon is a pure compression mode while the second mode a prolate/oblate mode, when viewed from the circular cross-section. However, these two modes are reversed for the cantaloupe. Simple and effective rules are thus proposed to distinguish them. The results of this work reveal that the vibrations of ellipsoidal fruits are more complicated and also different

from those of spherical ones.

Chem Codes: Chemical of Concern: PSM Rejection Code: CHEM METHODS.

This paper deals with a non-destructive firmness estimation method using vibrational characteristics for solid fruits of oblate ellipsoidal shape. In association with the previous work, a general estimation formula is proposed, which is suitable for both prolate and oblate solid ellipsoids. The applicable range of the new firmness index is at least between axis ratio of 0[middle dot]4 and 2[middle dot]0 from finite element simulations.

CAS Registry Numbers: 63-25-2 Role: ANT (Analyte), ANST (Analytical study) (detn. of, colorimetric) A rapid colorimetric method is developed to det. deposits of carbaryl (I) [63-25-2] insecticide on fruit tree foliage. Analyses take <3 min/sample when 50 or more samples are processed at a time. A 5 cm2 disk punched from a leaf is used for the detn. I is extd. and hydrolyzed by methanolic NaOH (0.03%) and then coupled with p-nitrobenzenediazonium tetrafluoroborate, which produces a spectrum of colors ranging from red to blue. In a concn. range of 0.5 10 mg/cm2 of leaf surface or 0.25-5 mg/mL of alk. soln. in a test tube, the color absorbance obeys Beer's law when measured at 580 nm. Little, if any, interference is obsd. from other commonly used pesticides, such as dicofol, tetradifon, azinphosmethyl, phosmet, captan, and folpet. If a spectrophotometer is not available, or when a rapid field test is required, a semiquant. detn. is also possible. [on SciFinder (R)] 0021-8561 carbaryl/ colorimetric/ detn

Natural alk. water samples collected from the Holland Marsh area and Niagara Region in Ontario, Canada had pH values in the range of 7.60-9.68, and their buffer capacity ranged from 0.21 * 10-3 to 2.00 * 10-3M. Adding 0.5 g of NH4H2PO4 or KH2PO4 per L of water lowered the pH of all samples tested to 6.7. The majority of pesticides are most stable at this pH and the probability of alk. hydrolysis occurring can be reduced by this simple procedure. <u>Chem Codes</u>: Chemical of Concern: PSM <u>Rejection Code</u>: VIRUS.

Summary Bacteriophage [phi]29 requires scaffolding protein to assemble the 450 x 540 A prolate prohead with T = 3 symmetry end caps. In infections with a temperature-sensitive mutant scaffolding protein, capsids assemble predominantly into 370 A diameter isometric particles with

T = 3 symmetry that lack a head-tail connector. However, a few larger, 430 A diameter, particles are also assembled. Cryo-electron microscopy shows that these larger particles are icosahedral with T = 4 symmetry. The prolate prohead, as well as the two isometric capsids with T = 3 and T = 4 symmetry, are composed of similar pentamers and differently skewed hexamers. The skewing of the hexamers in the equatorial region of proheads and in the T = 4 isometric particles reflects their different environments. One of the functions of the scaffolding protein, present in the prohead, may be to stabilize skewed hexamers during assembly.

Citations: Poulsen, M; Principles and Practices of Method Validation 2000, 108 The estn. of uncertainty of an anal. result has become important in anal. chem. It is esp. difficult to det. uncertainties for multiresidue methods, e.g. for pesticides in fruit and vegetables, as the varieties of pesticide/commodity combinations are many. In the present study, recommendations from the International Organization for Standardisation's (ISO) Guide to the Expression of Uncertainty and the EURACHEM/CITAC guide Quantifying Uncertainty in Anal. Measurements were followed to est. the expanded uncertainties for 153 pesticides in fruit and vegetables. Data from inhouse validation were used in the estn. of the uncertainty. No significant difference in the relative std. deviation for reproducibility (RSDR) were found between the different concn. levels at concn. levels exceeding 2.5 times the detection limit. Therefore, it was possible to pool the RSDR within a single matrix. However, a difference in RSDR between matrixes was seen, thus the poorest RSDR of the investigated matrixes was chosen for the uncertainty estn. The expanded uncertainties ranged from 7 to 78% with an av. of 32% and median of 32%. Furthermore, only RSDR contributed to the uncertainty estn. Chem Codes: Chemical of Concern: PSM Rejection Code: METHODS, MODELING.

The volume scattering strength of swim-bladdered fish is very sensitive to fish size, shape, and orientation. However, the appropriate geometrical and behavioral parameters necessary to determine these parameters are not always available. Inadequate knowledge of these parameters limits our ability to correctly estimate lengths and abundances of fish with acoustic technology. A method for extracting geometrical and behavioral parameters of individual fish using a scattering model-based echo-trace-analysis (ETA) is presented. The scattering model used in the ETA is based on the Kirchhoff approximation and a prolate spheroid is used to approximate the shape of the swimbladder. The geometric shape of a resolved echo from an individual fish is used in a least-squares algorithm to infer information about the swimming speed, direction, and orientation of the fish. The acoustic intensity distribution of an individual fish along a resolved echo trace is used in a least-squares algorithm to infer information about the size, aspect ratio, and orientation of the swimbladder. Results from the ETA were more sensitive to variations in vertical swimming speed and orientation of the swimbladder than to variations in horizontal swimming speed and aspect ratio of the swimbladder. The proposed ETA was applied to field data, a 38 kHz echogram of a school of Atlantic cod recorded with a Simrad EK500 echo sounder. The inferred sizes and orientations of a number of the resolved echo traces for individual fish were consistent with available observation data. One of the advantages of the ETA method presented here is that it can be easily extended to a dual beam, a split-beam, or a multi-beam acoustic system. Anal. was performed in the selected-ion monitoring mode, and the identities of the pos. analytes were confirmed by retention time and the ratios of selected ions. The selected ion mode demonstrated an acceptable selectivity for most of the pesticides detd. in 3 kinds of samples (Chrysanthemum coronarium; Perilla japonica, leaf; and Lactuca sativa, which are very popular vegetables eaten raw in Korea), and very minor interferences were obsd. in the elution area of the pesticide analytes. Samples were spiked with pesticides at 0.1-1.0 mg/kg. The recoveries of 90% of the pesticides were between 70 and 110%; however, the recoveries of acephate and folpet were very poor, i.e., <50%. The limits of detection (LODs) for most pesticides were between 0.02 and 0.3 mg/kg, and the LODs for about half of the pesticides studied were <0.05 mg/kg. [on SciFinder (R)] 1060-3271

255. Ciavatta, Liberato, Ferri, Diego, and Palombari, Roberto (1980). On the equilibrium Cu2+ + Cu(s) [right arrow over left arrow]2Cu+. *Journal of Inorganic and Nuclear Chemistry* 42: 593-598.
<u>Chem Codes</u>: Chemical of Concern: PSM <u>Rejection Code</u>: CHEM METHODS.

The equilibrium between Cu2+, copper metal and Cu+ ion has been studied, at 25[degree sign]C in a series of (Na)ClO4 as well as (Na2)SO4 ionic media, by passing Cu2+ solutions through a column of finely divided copper metal. In the effluent liquid phase, which was made to percolate at a rate low enough for equilibrium to be attained. the number of equivalents of reducing agent was determined by constant-current coulometry. The measurements were performed in 0.5, 1.2 and 3 M ClO4-, and 0.1, 0.2, 0.4 and 1 M SO42- ionic media. From the experimental data the equilibrium constant at infinite dilution log K0-5.73+/-0.03, for Cu2++Cu(s)[right arrow over left arrow]Cu+, has been evaluated by applying the specific interaction theory [15-17]. The standard potentials of the half-reactions involving the Cu+ ion have also been recalculated.

Abstract: The general public is concerned about potential environmental impacts of agrochemicals applied to turfgrass. It is especially important that certain industry standard turfgrass systems, such as USGA greens, be evaluated for potential environmental impact. The objective of this study was to assess the mobility and persistence of chlorpyrifos (O,O-diethyl-O-3,5,6-trichloro-2-pyridyl phosphorothioate), isazophos[O-[5-chloro-1-(methylethyl)-1H-1,2,4-triazol-3yl] O,O-diethyl phosphorothioate], isofenphos [1-methylethyl 2-[[ethoxy(1-methylethyl) amino] phosphinothioyl]oxy] benzoate], and ethoprop (O-ethyl S,S-dipropylphosphorodithioate) applied to a USGA cv. Tifdwarf bermudagrass (Cynodon dactylon x C. transvaalensis Burtt-Davy) green. The quantity of each organophosphate (OP) pesticide in turf clippings, thatch, soil, and percolate was determined over two application cycles, with the exception of ethoprop which was applied once. Pesticide recovery in clippings after a single application of fenamiphos (ethyl 3-methyl-4(methylthio)phenyl (1-methylethyl)phosphoramidate) and fonofos (O-ethyl-S-phenyl ethylphosphonodithioate) was determined, in addition to the above mentioned OP pesticides. For liquid formulations, less than 1% of the OP pesticides applied were found in clippings. However, nearly 8% of chlorpyrifos and 1.2% of fonofos was removed in clippings after a granular application. Total average pesticide removed in clippings after granular applications of ethoprop, chlorpyrifos, fenamiphos, and fonofos were 9.9, 9.2, 5.1, and 4.3 mg m superior - superior 2, respectively, while the largest amount from a liquid application of pesticide removed in clippings was 2.0 mg m superior - superior 2 of isofenphos. Less than 0.1% of the OP pesticides applied to the USGA green were recovered in percolate water, regardless of substantial variations in rainfall and total percolation. Most of the applied OP pesticides appeared to be retained in the thatch layer, where presumably they were microbially degraded over time.

Abstract: The Fabales clade comprises four families: Leguminosae, Polygalaceae, Quillajaceae and Surianaceae. This study presents new information on the pollen morphology of Quillaja, the only genus of Quillajaceae, and Recchia, Guilfoylia, Cadellia, Suriana and Stylobasium, the five genera that comprise Surianaceae. The pollen of 9 of the 11 species currently recognised within the two families was examined using light microscopy (LM), scanning electron microscopy (SEM) and, selectively, with transmission electron microscopy (TEM). Pollen of all taxa is isopolar with tri-zonocolporate apertures, lalongate endoapertures with fastigia adjacent to the endoaperture, and long ectoapertures that are nearly equal to the polar length. Apocolpia are correspondingly small. Quillaja pollen is subprolate to prolate, and striate with a granular aperture surface membrane. Ectexine protrudes over the endoapertures. In thin section the foot layer is thicker in mesocolpial areas and thin to discontinuous around the apertures, where the endexine is thicker. Cadellia pollen is prolate spheroidal, and striate with a granular aperture surface membrane. Exine protrudes over the endoapertures. In thin section the endexine is thicker and lamellate around the endoaperture area, and the foot layer is thicker in mesocolpial regions. Guilfoylia pollen is oblate and gemmate-verrucate, with a granular aperture surface membrane. Columellae are short. Recchia pollen is suboblate to oblate spheroidal, and microreticulate-perforate with a granular aperture surface membrane. Exine protrudes over the endoapertures. The foot layer is thin to discontinuous around aperture margins and thick in mesocolpial regions. Stylobasium pollen is suboblate, and finely rugulate-perforate with a granular aperture surface membrane. Columellae are short, the foot layer is thin or absent. Suriana pollen is suboblate, and finely rugulate-perforate with a granular aperture surface membrane. Pollen of Cadellia and Recchia, and Stylobasium and Suriana are morphologically similar. Verrucate surface

ornamentation is only present in Guilfoylia. Quillaja, Cadellia and Recchia share the character of protruding exine over the endoaperture area. Striate ornamentation occurs in Quillaja and Cadellia. The pollen morphology of Quillajaceae has more in common with that of Leguminosae and Surianaceae, and with Cadellia in particular, than with Polygalaceae. (copyright) 2004 Elsevier B.V. 259. Cleveland, Don W., Hwo, Shu-Ying, and Kirschner, Marc W. (1977). Physical and chemical properties of purified tau factor and the role of tau in microtubule assembly. *Journal of Molecular Biology* 116: 227-247.
<u>Chem Codes</u>: Chemical of Concern: PSM <u>Rejection Code</u>: CHEM METHODS.

This paper describes the physical and chemical properties of purified tau, a protein which is associated with brain microtubules and which induces assembly of microtubules from tubulin. Purified tau is composed of four polypeptides which migrate at positions equivalent to molecular weights between 55,000 and 62,000 during electrophoresis on sodium dodecyl sulfate/polyacrylamide gels. These polypeptides are shown to be closely related by peptide mapping and by amnio acid analysis. A comparison by various techniques of the high molecular weight microtubule-associated proteins with the tau polypeptides indicates no apparent relationship. Tau is found by analytical ultracentrifugation and by sedimentation equilibrium to have a sedimentation coefficient of 2.6 S and a native molecular weight of 57,000. Tau, therefore, must be highly asymmetric (an axial ratio of 20:1 using a prolate ellipsoid model), and yet possess little [alpha]-helical structure as indicated by circular dichroism. Isoelectric focusing shows tau to be a neutral or slightly basic protein. Tau is also seen to be phosphorylated by a protein kinase which copurifies with microtubules. In the assembly process, tau apparently regulates the formation of longitudinal oligomers from tubulin dimers, and hence promotes ring formation under depolymerizing conditions and microtubule formation under polymerizing conditions. The known asymmetry of the tau molecule suggests that tau induces assembly by binding to several tubulin molecules per tau molecule, thereby effectively increasing the local concentration of tubulin and inducing the formation of longitudinal filaments. The role of tau is discussed in light of reports of polymerization induced by particular non-physiological conditions and by various polycations. The formation of normal microtubules over a wide range of tubulin and tau concentrations under mild buffer conditions suggests that tau and tubulin define a complete in vitro assembly system under conditions which approach physiological.

<u>Chem Codes</u>: Chemical of Concern: PSM <u>Rejection Code</u>: FATE.

ABSTRACT: BIOSIS COPYRIGHT: BIOL ABS. Groundwater contamination by pesticides may be affected by the amounts of pesticide used, the mobility and degradation characteristics of the pesticides, and the vulnerability of an area to pollution. An index of potential pollution was developed based on these factors, with the groundwater vulnerability being measured using the DRASTIC ranking method. Seventeen regions were selected from throughout New Zealand where

significant pesticides have been applied and there is an underlying groundwater system. They were ranked according to this index of potential pollution. The sensitivity of the ranking to various formulation and weightings of the index was examined. Three regions (Poverty Bay, Te Puke, and Motueka) were generally highly ranked for a wide range of index formulations. Six of the higher-ranked regions were selected for sampling in the second phase of the study.

262. Cofie, O. O., Agbottah, S., Strauss, M., Esseku, H., Montangero, A., Awuah, E., and Kone, D. (Solid-Liquid Separation of Faecal Sludge Using Drying Beds in Ghana: Implications for Nutrient Recycling in Urban Agriculture. *Water res. 2006, jan; 40(1):75-82. [Water research]: Water Res*. Chem Codes: Chemical of Concern: PSM Rejection Code: FATE, CHEM METHODS.

ABSTRACT: This study investigated the possibility of recycling nutrients in human excreta and municipal solid waste for use in agriculture. It reports on the use of drying beds in separating solid and liquid fractions of faecal sludge (FS) so that the solids can be co-composted and the organic matter and part of the nutrients captured for urban agriculture. Sludge influent onto drying beds, percolate effluent, and dewatered sludge (biosolids) were monitored over eight loading cycles in 2002. The unplanted drying beds were made of 15 cm of sand (0.2-0.6mm diameter) and 25 cm gravel (10 and 19 mm diameter). The loading rate of sludge ranged from 196 to 321 kg total solids (TS) /m(2)y. Biosolids with TS 20% were obtained after an average drying time of 2 weeks. The drying beds retained 80% of solids and 100% of helminth eggs. The biosolids had average organic matter content of 61%; hence, allowing for co-composting with biodegradable organic solid waste for hygienisation. The process is being investigated further to attain higher efficiency and reliability.

263. Cohen, M. E. (1993). Bursts of Periodontal Destruction and Remission, Percolation Phase Shifts, and Chaos. *Journal of periodontal research* 28: 429-436.
Chem Codes: Chemical of Concern: PSM Rejection Code: HUMAN HEALTH.

ABSTRACT: BIOSIS COPYRIGHT: BIOL ABS. Bursts of periodontal destruction are modelled as percolation-driven phase shift events. Percolation theory, though widely used to study the flow of liquids through porous nonliving materials (e.g., soils and rocks), can be applied to bacterial or toxicological penetration of living tissue in only an approximate sense. However, it seems necessary that some mechanism, fundamentally similar to the percolation phase shift, is required to adequately account for bursts. Percolation theory is therefore offered as a framework for considering such events. A principal finding of percolation theory is the existence of percolation thresholds, such that when P, the independent probability that a subregion is susceptible to an invading substance, is above the threshold, the region will percolate or allow flow through, and when P is below the threshold the region will not percolate. This instantaneous transition, from a structure that will permit percolation to one that will not, is

264. Colfen, H., Berth, G., and Dautzenberg, H. (2001). Hydrodynamic studies on chitosans in aqueous solution. *Carbohydrate Polymers* 45: 373-383.
Chem Codes: Chemical of Concern: PSM Rejection Code: CHEM METHODS.

Three commercial chitosans with a degree of acetylation of 25-30% were studied by light scattering (static and dynamic), analytical ultracentrifugation (sedimentation velocity and sedimentation equilibrium), and capillary viscometry in 0.02 M acetate buffer/0.1 M NaCl, pH 4.5. The molecular masses obtained by sedimentation equilibrium measurements or sedimentation and diffusion coefficients according to the Svedberg equation agreed well or fairly well with those from static light scattering whereas the molecular masses calculated via the Scheraga-Mandelkern equation were found too low by almost 50%. The various Mark-Houwink type relationships suggested a nearly free-draining flexible worm-like chain. A prolate ellipsoid of revolution with an axial ratio a/b~25 was shown to be a hydrodynamically equivalent body of the flexible worm-like chain that had been derived from static light scattering. The findings illustrate the fact that a hydrodynamically strongly asymmetric shape need not mean a strongly elongated shape of the molecules in reality. ABSTRACT: TD3: Residues of phosmet were measured on samples of apples and leaves and in soil and water collected during the 1987 apple maggot fruit fly treatment program. The samples were analyzed to examine the dissipation of phosmet over time between successive sprays. The effect of climate on the environmental fate of phosmet was studied by monitoring and comparing results from one coastal and two inland sites. Residue levels in 1987 were lower for soil and higher for fruit than those levels found in 1986. Quality control samples indicated that these differences may have been attributed to a change in the laboratory that conducted the analyses. The 10 ppm tolerance level for apple fruit was exceeded in only one sample collected the day after phosmet was applied. At both inland sites, phosmet levels on fruit samples taken the day following applications were higher with successive applications. Possibly, shorter spray intervals accounted for the trend. No phosmet or phosmetoxon was detected (detection limit 1

267. Connors, Peter G. and Beeman, W. W. (1972). Size and shape of 5 s ribosomal RNA. *Journal of Molecular Biology* 71: 31-37.
Chem Codes: Chemical of Concern: PSM Rejection Code: BACTERIA, YEAST.

The X-ray scattering at small angles from dilute solutions of yeast and Escherichia coli 5 s RNA has been measured. The molecule is prolate with an axial ratio of about 5 to 1. The radius of gyration is Rg=34.5 +/- 1.5 A. A comparison of the experimental and computed scattering curves suggests that one end of the molecule may be appreciably larger in cross-section than the other. There is indirect evidence for the existence of double helical segments parallel to the long axis of the molecule. The scattering curves from the 5 s RNA's of the two different organisms are the same within experimental error. http://www.sciencedirect.com/science/article/B6WK7-4DNGVF2-42/2/b1b90ef58260694774a36b5aa5263763

Citations: 28) Anon; Florida Administrative Code 1995, Part 5 Improved quality and efficiency of pesticide residue anal. were achieved by examg. all aspects of the lab. process. In an effort to eliminate methylene chloride hazardous waste, an acetonitrile extn. method, originally developed by the California Department of Agriculture, was modified and adopted. Sample size and solvent consumption were reduced with the new method. Custom glassware racks and disposable supplies reduced overall anal. time. Gravity-fed, solid-phase extn. simplified sample prepn. and provided cleaner exts. for gas chromatog. analyses. Modifications to the method were made to achieve the ruggedness needed to maintain quality objectives during routine anal. Instrumental improvements, including new selective detectors, retention time locking, and mass spectrometry screening for all samples, provided the lab. with efficient, reliable, and confirmed anal. results. Chem Codes: Chemical of Concern: PSM Rejection Code: CHEM METHODS.

The binding of n-octyl glucoside to a range of ten globular proteins in aqueous solution (pH 6.4, ionic strength 0.132) at 25[degree sign]C has been measured by equilibrium dialysis. The binding isotherms which rise steeply at free n-octyl glucoside concentrations below the critical micelle concentration have been fitted to the Hill equation. For all the proteins the Hill coefficients are greater than unity indicating that binding is a positively cooperative process and the Gibbs energies of binding lie in a range from -9.7 kJ mol-1 for bovine serum albumin to -11.4 kJ mol-1 for fibrinogen and Aspergillus niger catalase. The enthalpies of interaction have been measured directly by microcalorimetry and are found to be very small relative to the Gibbs energies of binding consistent with a hydrophobic interaction. No evidence was found for the denaturation of the proteins by octyl glucoside. Binding has been analysed and discussed in terms of a model in which the proteins are incorporated into an octyl glucoside micelle. On this basis saturation binding to ribonuclease, lysozyme and [alpha]-chymotrypsin would be satisfactorily described in terms of a prolate ellipsoidal micelle whereas for bovine and Aspergillus niger catalase on oblate ellipsoid would describe the data more satisfactorily. Citations: Zahm, S; Am J Ind Med 2001, 40, 487 Little is known about pesticide exposure among farm workers; even less is known about exposure assocd. with performing specific farm tasks. Using a random sample of 213 farmworkers in 24 communities and labor camps in eastern Washington State, the assocn. between occupational task and organophosphate (OP) pesticide residues in dust and OP metabolite concns. in urine samples of adult farm workers and their children was assessed. Data were from a larger study which sought to test a culturally appropriate intervention to break the take-home pathway of pesticide exposure. Commonly reported farm tasks were harvesting or picking (79.2%), thinning (64.2%), loading plants or produce (42.2%), planting or transplanting (37.6%), and pruning (37.2%). Mixing, loading, or applying pesticide formulations was reported by 20% of the sample. Workers who thinned were more likely than those who did not to have detectable concns. of azinphos-Me in house dust (92.1% vs. 72.7%; $p = 0.001$) and vehicle dust (92.6% vs. 76.5%; $p = 0.002$). Thinning was assocd. with higher urinary pesticide metabolite concns. in children (91.9% detectable vs. 81.3%; $p = 0.02$), but not in adults. Contrary to expectation, workers who reported mixing, loading, or applying pesticide formulations had lower detectable levels of pesticide residues in house or vehicle dust vs. those who did not perform these job tasks, though differences were not significant. Future research should evaluate workplace protective practices for field workers and the adequacy of re-entry intervals for pesticides used during thinning. 275. Cox, E. R. (Preliminary Study of Wastewater Movement in Yellowstone National Park, Wyoming, October 1976 Through September 1977. *Govt reports announcements & index*

(gra&i), issue 06, 1984.
Chem Codes: Chemical of Concern: PSM Rejection Code: FATE.

ABSTRACT: TD3: This report describes hydrologic data collected and some preliminary interpretations for a study by the US Geological Survey in cooperation with the National Park Service to determine the effects on nearby lakes and streams of wastewater effluents that percolate from sewage lagoons at four sites in Yellowstone Natinal Park. A network of observation wells has been established near the sites, and water-level and water-quality data have been collected. Ground-water mounds have built up under the lagoons as percolation of effluents occurred. Percolating effluents mix with ground water and move down the hydraulic gradient in a direction generally perpendicular to the water-level contours. Chloride and sulfate concentrations and specific conductance of water in wells, and water-level contours indicate the most likely areas and directions of movement of percolating effluents. The most likely directions of movement are: Fishing Bridge, southwestward toward the Yellowstone River; Old Faithful, northward

Abstract: The Turonian flora from Sayreville New Jersey includes one of the world's most diverse assemblages of Cretaceous angiosperm flowers. This flora is made even more interesting by its association with a large insect fauna that is preserved by charcoalification as well as in amber. Floral diversity includes numerous representatives of Magnoliidae, Hamamelididae, Rosidae, Dilleniidae, and Asteridae (Ericales sensu lato). Included are hypogynous, five-merous flowers with uniseriate hairs on the pedicels and stamens in bundles most frequently borne opposite the petals. There is considerable variation in filament length, and some filaments are branched. On some anthers, strands of residue, suggesting the former presence of a liquid of unknown nature, partially occlude the apparent zone of dehiscence. In other cases, open anthers are fully occluded by an amorphous substance. Pollen is rarely found associated with anthers, but is common on stigmatic surfaces. Pollen is prolate and tricolporate with reticulate micromorphology. The superior syncarpous ovary is five-carpellate with axile/intruded parietal placentation and numerous anatropous ovules/carpel. Ovary partitions have closely spaced, parallel ascending channels (secretory canals?), and there are apparent secretory canals/cavities in receptacles, sepals, and petals. Individual stigmas are cuneiform with a central groove and eccentrically peltate. Styles are short and fused. In aggregate, the stigmas form a secondarily peltate stigma. Seeds have a reticulate sculpture pattern, a pronounced raphe, and funicular arils with sculpture similar to the seeds. Phylogenetic analyses of several data matrices of extant taxa place this fossil in a monophyletic group with the modern genera Garcinia and Clusia within the Clusiaceae. As such, these fossils represent the earliest fossil evidence of the family Clusiaceae. Some modern Clusiaceae are notable, in particular, for their close relationship with meliponine and other highly derived bee pollinators; the fossil flowers share several characters that suggest a similar mode of pollination. This possibility is consistent with other floral and insect data from the same locality. 52 refs.

278. Cristina Forti, M. and Neal, Colin (1992). Hydrochemical cycles in tropical rainforests: an overview with emphasis on Central Amazonia. *Journal of Hydrology* 134: 103-115.
Chem Codes: Chemical of Concern: PSM Rejection Code: FATE.

The ionic content of the solutions found in the hydrological cycle component that cross the aerial phytomass (rainfall and throughfall), percolate through the root zone and drain to streams, for tropical rainforest, particularly in Central Amazonia, is examined. The rain waters in tropical rainforest are, in general, acidic and they provide the main chemical input to the rainforest ecosystem. The cycling of elements in the ecosystem, dominated by the transfer of compounds between throughfall and soil solution at shallow depth, contributes a much greater flux than that from rainfall input and stream output. http://www.sciencedirect.com/science/article/B6V6C-48C7D50-5G/2/43b1db7a13bddde3345b6b0a46578791

279. Crites, R. W. and Uiga, A. (An Approach for Comparing Health Risks of Wastewater Treatment Alternatives: a Limited Comparison of Health Risks Between Slow Rate Land Treatment and Activated Sludge Treatment and Discharge. *Govt reports announcements & index*

(gra&i), issue 21, 1979.
Chem Codes: Chemical of Concern: PSM Rejection Code: FATE.

ABSTRACT: TD3: The objective of this report is to develop an approach for comparing the health effects of land treatment and conventional treatment and discharge systems. An example assessment between activated sludge and slow rate land treatment of wastewater was presented based on the following assumptions: Flow of 3 Mgal/d of domestic wastewater. Activated sludge flowsheet with (1) disinfection and (2) surface water discharge. Slow rate land treatment flowsheet with (1) aerated lagoon preapplication treatment, (2) storage, (3) no disinfection, and, (4) percolate water recovery by underdrains and surface water discharge. The qualitative results indicate that both conventional and land treatment systems, which are well maintained and have good operating conditions, provide a large measure of safety for public health. Land treatment systems that involve slow infiltration offer greater protection against parasites and viruses, trace metals, nitrate, trace organics, and halogenated organics. Technical rept.

ISSN: 0028-646X
Abstract: Concentrations of NH inferior 4 superior +, NO inferior 3 superior -, PO inferior 4 superior 3 superior -, K superior +, Ca superior 2 superior + and Mg superior 2 superior + in snow meltwater resulting from summer snow showers were monitored before and after its passage through monospecific stands of the Antarctic macrolichen Usnea sphacelata R. Br. The sampling was conducted under field conditions near Casey Station in East Antarctica between January and March. Total snow deposition during the 61-d period was 44 plus-or-minus 1 mm (rainfall equivalent depth) delivering 362 plus-or-minus 10, 87 plus-or-minus 2 and 9 plus-or-minus 1 mu mol m superior - superior 2 of NH inferior 4 superior +, NO inferior 3 superior - and PO inferior 4 superior 3 superior -, respectively. Meltwater that had percolated through U. sphacelata was depleted in NH inferior 4 superior + and NO inferior 3 superior - equating with a retention by the lichen of 87 and 92%, respectively, of the total wet deposition of these ions. Lichen-modified meltwater was slightly enriched in PO inferior 4 superior 3 superior -, but because the volume of the lichen percolate was smaller than that of the original snow deposition, the lichen achieved a net gain of 9% of the total P deposited. Lichen percolate was also enriched in metal cations. Potassium loss associated with the melting of the heaviest snowfall (18 mm) was equivalent to only 0.05% of the total K in the lichen suggesting that ion loss did not signal significant cellular damage. There was also a progressive increase in NH inferior 4 superior + concentration in unmodified meltwater from 3 to 21 nmol ml superior - superior 1 over a 3-d period whereas levels in the lichen-modified meltwater remained unchanged at less than or equal 4 nmol ml superior - superior 1. This enrichment in NH inferior 4 superior + might have resulted from dry deposition onto the melting snow pack of NH inferior 3 emitted from nearby penguin rookeries. During the study, tagged thalli of U. sphacelata made a 2% loss in dry mass although they appeared healthy and, at the end of the study, showed an effective quantum yield (Delta F/Fm') comparable with field material. The results are discussed in relation to the time of year that is likely to be most suitable for lichen growth in this continental Antarctic environment and the potential growth-led demand for N in U. sphacelata.

Citations: 39) Hall, L; J Mol Graphics Modell 2001, 20, 4 This study reports a database of toxicity values for 91 compds. assessed in a novel, rapid, and economical 15 min algal toxicity test. The toxicity data were measured using the unicellular green alga Chlorella vulgaris in an assay that detd. the disappearance of fluorescein diacetate. The chems. tested covered a wide range of physicochem. properties and mechanisms of action. Quant. activity-activity relationships with the toxicity of the chems. to other species (Tetrahymena pyriformis, Vibrio fischeri, and Pimephales promelas) showed strong relationships, although some differences resulting from different protocols were established. Quant. structure-activity relationships (QSARs) were detd. using linear [multiple linear regression (MLR)] and nonlinear [k-nearest neighbors (KNN)] methods. Three descriptors, accounting for hydrophobicity, electrophilicity, and a function of mol. size cor. for the presence of heteroatoms, were found to be important to model toxicity. The predictivity of MLR was compared to KNN using leave-one-out cross-validation and the simulation of an external test set. MLR demonstrated greater stability in validation. The results of this study showed that method selection in QSAR is task-dependent and it is inappropriate to resort to more complicated but less transparent methods, unless there are clear indications (e.g., inability of MLR to deal with the data set) for the need of such methods. Chem. processes included 1 ppm of aq. O_3, 1% H_2O_2, 100 ppm of Cl, and UV, whereas photochem. processes included H_2O_2/UV, Cl/UV, and O_3/H_2O_2/UV. Phosmet applied as Imidan 2.5EC under lab. conditions resulted in a mean residual concn. of 44.4 ppm, which was significantly degraded ($p < 0.05$) by O_3 and Cl, yielding redns. of 57.7 and 46%, resp. Interaction between phosmet (Imidan 2.5EC) and any chem. or photochem. treatment did not result in conversion to phosmet oxon. Residual anal. of com. grown blueberries revealed mean phosmet (Imidan 70W) levels of 10.65 ppm and phosmet oxon levels of 12.49 ppm. Treatment of com. blueberries resulted in significant redns. in phosmet regardless of treatment type; however, only UV, H_2O_2/UV, and O_3 treatments degraded phosmet (Imidan 70W) to less toxic metabolites and reduced phosmet oxon levels. Treatment-induced conversion of phosmet to phosmet oxon was

noticeably influenced by variations between phosmet formulations. Acceleration of photochem. degrdn. by UV was not obsd. Selective oxidn. by O3 represents a significant postharvest process for degrading residual phosmet on lowbush blueberries. In 1976 a monitoring program started for the control of pesticide contamination of surface waters in Hungary. The monitoring program regularly gives information on the pesticide distribution in surface waters and the effect of the Hungarian pest management practice on the environment, in order to develop a sustainable pest management system. The data show that pest management in cooperative farms do not cause any real damage to the aquatic ecosystem. [on SciFinder (R)] pesticide/ water/ pollution/ Hungary

Chem Codes: Chemical of Concern: PSM Rejection Code: HUMAN HEALTH.

ABSTRACT: BIOSIS COPYRIGHT: BIOL ABS. Foods, in addition to supplying the nutrients, vitamins, and minerals necessary to sustain life, may also contain a variety of naturally-occurring toxins in varying quantities. While some of these can present a health risk to the consuming public, usually when certain food items are not prepared properly, research has identified a beneficial role for some in helping to prevent illness. A more important risk derives from the synthetic compounds, such as pesticides, that may contaminate foods. Recent debate among scientists and government policy makers, reported widely in both the scholarly and popular press, has sought to clarify the relative public health risks presented by natural toxins versus pesticidal residues present in foods. An attempt is made here to put this debate in proper perspective. Information is given on the role played by naturally-occurring food components in promoting human health, followed by a survey of the diversity of natural toxins present in ma

These products contain a high lipid content, which can adversely affect pesticide recoveries and harm traditional chromatog. systems. For extn., the main factors (oil and water content) were studied and optimized in expts. to maximize pesticide recoveries. Dispersive SPE with different sorbents was also investigated to minimize matrix coextractives and interferences. For anal., a new automated DSI device was tested in GC-MS to avoid nonvolatile coextractives from contaminating the instrument. LC-MS/MS with pos. ESI was used for those pesticides that were difficult to detect by GC-MS. The final method was validated for olives in terms of recoveries, repeatabilities, and reproducibilities using both detection techniques. The results demonstrated that the method achieved acceptable quant. recoveries of 70-109% with RSDs <20% for DSI-GC-MS and 88-130% with RSDs <10% for LC-MS/MS, and LOQ at or below the regulatory max. residue limits for the pesticides were achieved. House dust samples (n = 156) were collected from within the homes, and vehicle dust samples (n = 190) were collected from the vehicles used by the farm workers to commute to and from work. Urine samples were obtained from a farm worker (n = 213) and a young child (n = 211) in each household. Dust samples were analyzed for six pesticides, and urine samples were analyzed for five dialkyl phosphate (DAP) metabolites. Azinphosmethyl was detected in higher concns. (p < 0.0001) than the other pesticides: geometric mean concns. of azinphosmethyl were 0.53 mg/g in house dust and 0.75 mg/g in vehicle dust. Di-Me DAP metabolite concns. were higher than di-Et DAP metabolite concns. in both child and adult urine (p < 0.0001). Geometric mean di-Me DAP concns. were 0.13 mmol/L in adult urine and 0.09 mmol/L in child urine. Creatinine-adjusted geometric mean di-Me DAP concns. were 0.09 mmol/g in adult urine and 0.14 mmol/g in child urine. Azinphosmethyl concns. in house dust and vehicle dust from the same household were significantly assocd. (r2 = 0.41, p < 0.0001). Di-Me DAP levels in child and adult urine from the same household were also significantly assocd. (r2 = 0.18, p < 0.0001), and this assocn. remained when the values were creatinine adjusted. The results of this work support the hypothesis that the take-home exposure pathway contributes to residential pesticide contamination in agricultural homes where young children are present. 287. Cusack, Stephen, Oostergetel, Gert T., Krijgsman, Peter C. J., Mellema, Jan E., and Klug, A. (1983). Structure of the top a-t component of alfalfa mosaic virus a non-icosahedral virion. *Journal of Molecular Biology* 171: 139-155.
Chem Codes: Chemical of Concern: PSM Rejection Code: VIRUS.

Neutron-scattering in combination with quasi-elastic light-scattering and electron microscopy was used to derive a model for the capsid structure of the Top a-t component of alfalfa mosaic virus (AMV-Ta-t). In the electron microscope, AMV-Ta-t appears as an irregular ellipsoidal particle with apparent dimensions 275(+/-31) x225(+/-22) . Assuming that the particles are monodisperse, model calculations show that the neutron-scattering data are best explained by an oblate ellipsoidal shape for the virion with external dimensions 284 x284 x216 . Based on this result, and in combination with the known composition of the virion, it is suggested that the capsid structure could be based on a deltahedron with 52 pointgroup symmetry and comprising 120 subunits. Such a model would imply a greater deviation from equivalent subunit interactions than normally necessary in icosahedral capsids. The neutron and photon correlation data, however, do not allow us to rule out the possibility that Top a-t is a slightly polydisperse preparation of irregular prolate shapes with mean dimensions 312 x232 x232 . Both possibilities support the concept of alfalfa mosaic virus coat protein being capable of a wide range of intersubunit interactions, this flexibility resulting in considerable polymorphism in capsid structures.

289. Dall'Aglio, Mario, Duchi, Vittorio, Minissale, Angelo, Guerrini, Adolfo, and Tremori, Marco (1994). Hydrogeochemistry of the volcanic district in the Tolfa and Sabatini Mountains in central Italy. *Journal of Hydrology* 154: 195-217.
Chem Codes: Chemical of Concern: PSM Rejection Code: FATE.

A geochemical study on 26 thermal springs and 5 samples from thermal wells (t > 20[degree sign]C), 19 cold springs, 11 cold gas pools, and 14 stream samples from the Tolfa and Sabatini Mountains volcanic district (about 1300 km2) has clarified their genesis and evolution. Meteoric waters infiltrate the more permeable exposed rocks (carbonates and/or volcanites) and percolate down into two main aquifers. One is deep and located in Mesozoic anhydritic-carbonate formations, and is the regional geothermal reservoir that feeds springs that emerge at the margins of the carbonate series (either exposed or barely covered); its waters display typical bicarbonate-sulfate alkaline earth composition. The other aquifer(s) is shallower, consisting of waters that circulate primarily in volcanic deposits. The chemical characteristics of these shallow waters are heavily influenced by lithology and by a gas phase, mainly CO2, originating at depth. Temperature estimates obtained with SiO2 and gas geothermometers, which seem to be the most reliable under these conditions, indicate the widespread occurrence of deep fluids at temperatures higher than 110[degree sign]C under the area covered by the Sabatini volcanites. In some areas (Manziana, Trevignano, Nepi, and Cesano) the subsurface waters reach temperatures within the range characteristic of medium to high enthalpy systems (120-160[degree sign]C).

Combination with mass spectrometric detection is desirable for unambiguous confirmation of target compds. and the provisional identification of unknowns. A GC*GC system using a cryogenic modulator was coupled to a time-of-flight mass spectrometric (TOF MS) detector. With the detn. of pesticides in vegetable exts. as an example, it was demonstrated that GC*GC improves the sepn. dramatically. All 58 pesticides of interest could be identified using their full-scan mass spectra, which was not possible when using 1D-GC-TOF MS. In addn., the high scan speed of the TOF MS allowed the deconvolution of compds. partly co-eluting in GC*GC. [on SciFinder (R)] 0021-9673 pesticide/ detn/ vegetable/ GC/ TOF/ MS

comprehensive two-dimensional gas chromatog. coupled to time-of-flight mass spectrometry (GC * GC-TOF MS) was studied. The system was characterized with respect to the repeatability of peak areas and retention times of selected analytes, their detection limits, and the linearity of their calibration plots. The system was found to be linear in the 0.01-3 ng range, and detection limits for the pesticides were between 5 and 23 pg. The performance of the system was compared with that of conventional one-dimensional (1D) GC-TOF MS, the advantages of TOF MS for identification and deconvolution are discussed, and several approaches for the processing of GC * GC-TOF MS data are explained with the emphasis on (semi)-automated data processing and the differences with 1D-GC-TOF MS. Rearrangements and fragmentation by simple cleavage are postulated from analogy with similar compds., from the presence of Cl atoms with their readily-recognizable isotopic distribution when applicable, from elemental compns. detd. by accurate mass measurements, and, in a few cases, from model compds. The compds. are divided into 4 groups: phosphorodithioates, phosphorothionates, phosphorothiolates, and phosphates. The base peaks are formed by rearrangements and simple cleavage. Rearrangement ions are formed by (1) H migration from the alkyl ester group to the thiophosphite-O skeleton; (2) migration of H from the Z moiety (aryl or alkyl group) to the P-O skeleton; (3) migration of H from the Z moiety to the thiophosphite-O skeleton; (4) migration of H from the ester group bonded to P to the Z moiety; and (5) alkyl migration to the Z moiety. The base peak does not characterize the different groups or compds. within a group. However, beta-cleavage (relative to the Z moiety) producing relatively intense peaks (with the charge on the Z moiety) is characteristic of a given group. These data may be useful in identifying metabolites isolated from crops field-sprayed with an individual parent organophosphorus pesticide. Comparison of the field ionization and electron impact spectra of 31 complex org. mol. indicates that field ionization offers structural information which complements electron impact data. Mol. ion intensities were enhanced by field ionization for the compds. examd. Metastable peaks were observed only for those processes involving mol. ion decompns. Rearrangement and multistep processes were quite common, but those processes involving expulsion of CO as a neutral mol. and McLafferty rearrangements are in general of only minor importance in field ionization of org. mols. COMMENTS: Erratum in: Mol Gen Genet 1992 Jun;233(3):491
ABSTRACT: The Escherichia coli acid phosphatase gene appA is expressed in response to oxygen deprivation and is positively controlled by the product of appR (katF) which encodes a putative new sigma transcription-initiation factor. However, transcription of appA from its nearest promoter (P1) did not account for total pH 2.5 acid phosphatase expression and was not subject to regulation. The cloned region upstream of appA was extended and analyzed by insertions of transposon TnphoA and by fusions with lacZ. It contains two new genes, appC and appB, which both encode extracytoplasmic proteins. appC and appB are expressed from a promoter (P2) lying just upstream of appC. Both genes are regulated by oxygen, as is appA, and by appR gene product exactly as previously shown for appA. Analysis of the nucleotide sequence and of the origins of transcription have confirmed that the P2-appC-appB- (ORFX)-P1-appA region is organized on the chromosome as an operon transcribed clockwise from P2 and that P1 is a minor promoter for appA alone. Genes appC and appB encode proteins of Mr 58,133 and 42,377, respectively, which have the characteristics of integral membrane proteins. The deduced amino acid sequences of appC and appB show 60% and 57% homology, respectively, with subunits I and II of the E. coli cytochrome d oxidase (encoded by genes cydA and cydB). The notion that the AppC and AppB proteins constitute a new cytochrome oxidase or a new oxygen-detoxifying system is supported by the observation of enhanced sensitivity to oxygen of mutants lacking all three genes, cyo (cytochrome o oxidase), cyd (cytochrome d oxidase) and appB, compared to that of cyo cyd double mutants.

Abstract: Groundwater is being used extensively in the Delhi area for both irrigation and raw water requirement. Fluoride contamination in groundwater is therefore a matter of concern for the planners and managers of water resources. Stable isotope (super(18)O) and fluoride signatures in groundwater have been discussed, in this context, to characterise the sources and controlling processes of fluoride contamination. The study indicates that almost 50% of the area is affected by fluoride contamination beyond the maximum permissible limit. The wide range (0.10-16.5 ppm) in fluoride concentration suggests contributions from both point and non-point sources. Very high fluoride levels in groundwater are mostly found in the vicinity of brick kilns. Significant quantities of evaporated (isotopically enriched) rainfall, irrigation water and surface runoff water from surrounding farmland also percolate along with fluoride salts from the soils to the groundwater system. The process of adsorption and dispersion of fluoride species in the soil as well as lateral mixing of groundwater along specific flow-paths control the groundwater fluoride and super(18)O composition. The groundwater system has more than two isotopically distinct non-point source origins, causing spatial and temporal variations in fluoride concentration. Issues related to harmful

effects of excessive use of high-fluoride groundwater and management options have also been discussed.

299. Davey, Graham P., Ward, Lawrence J. H., and Brown, Julie C. S. (1995). Characterisation of four Leuconostoc bacteriophages isolated from dairy fermentations. *FEMS Microbiology Letters* 128: 21-25.
Chem Codes: Chemical of Concern: PSM Rejection Code: VIRUS.

Four bacteriophages (phages) growing on the same Leuconostoc strain were characterised. Electron micrographs showed these phages to be similar in morphology to the commonly isolated lactococcal phages with head diameters ranging from 49-55 nm and tail lengths of 117-131 nm. A distinctive base plate and collar were also present. From restriction enzyme analysis of purified phage DNA, the genome sizes were 23-29 kb. All four phages showed one major structural protein (of approximately 24 kDa) on SDS polyacrylamide gels. Hybridization experiments confirmed that the phages belonged to the same homology group. There was no homology between DNA from these phages and DNA from a prolate or small isometric lactococcal phage. Leuconostoc/ Bacteriophage/ Electron microscopy/ Phage protein/ Hybridisation

Chem Codes: Chemical of Concern: PSM Rejection Code: SURVEY.

ISSN: 0556-3321
Abstract: The pollen morphology of 22 species of Inula L. (s.str.) and its allied genera has been examined from Pakistan and Kashmir by light and scanning electron microscopy. Pollen grains are usually radially symmetrical, isopolar, prolate-spheroidal rarely oblate-spheroidal, tricolporate occasionally tetracolporate, zonoaperturate. Sexine slightly thicker than nexine or as thick as nexine. Tectum echinate, spines with acute-acuminate or rounded apices. On the basis of pollen size and tectum pattern in between spines, 3 major pollen types viz., Pollen type I: Duhaldea cappa, Pollen type II: Inula acuminata, Pollen type III: Pentanema divaricatum are recognized.

303. de Boer, Rob J. and Hogeweg, Pauline (1989). Idiotypic networks incorporating T-B cell co-operation. The conditions for percolation. *Journal of Theoretical Biology* 139: 17-38.
Chem Codes: Chemical of Concern: PSM Rejection Code: MODELING.

Previous work was concerned with symmetric immune networks of idiotypic interactions amongst B cell clones. The behaviour of these networks was contrary to expectations. This was caused by an extensive percolation of idiotypic signals. Idiotypic activation was thus expected to affect almost all (>107) B cell clones. We here analyse whether the incorporation of helper T cells (Th) into these B cell models could cause a reduction in the percolation. Empirical work on idiotypic interactions between Th and B cells however, would suggest that two different idiotypic Th models should be developed: (1) a Th which recognises native B cell idiotypes, i.e. a non-MHC-restricted "ThId" model, and (2) a "classical" MHC-restricted helper T cell model. In the ThId model, the Th-B cell interaction is symmetric. A 2-D model of a Th and a B cell clone that interact idiotypically with each other accounts for various equilibria (i.e. one virgin and two immune states). Introduction of antigen does indeed lead to a state switch from the virgin to the immune state; such a system is thus able to "remember" its exposure to antigen. Idiotypic signals do however, percolate in ThId models via these "B-Th-B-Th" pathways: proliferating Th and B cell clones that interact idiotypically, will always activate each other reciprocally. In the MHC-restricted Th model, Th-B interactions are asymmetric. Because the B cell idiotypes are processed and subsequently presented by MHC molecules, the Th receptor and the native B cell receptor are not expected to be complementary. Thus the Th and the B cells are unable to activate each other reciprocally, and a 2-D Th-B cell model cannot account for idiotypic memory. In contrast to the ThId model, idiotypic activation cannot percolate via "B-Th-B-Th" interactions. Due to the assymmetry idiotypic activation stops at the first Th level. A Th clone cannot activate a subsequent B cell clone: if the B cells recognise the Th cells, they see idiotype but get no help; if the Th cells see the B cells, the B cells are helped but see no idiotype. The percolation along "B-B-B" pathways in these two models is next analysed. Two B cells clones, each helped by one Th clone, are connected by a symmetric idiotypic interaction. It turns out that in both models the second (i.e. anti-idiotypic) B cells (B2) never proliferate. The anti-idiotypic B cells are activated whenever the first (idiotypic) B cells (B1) proliferate, but because the activated B2 cells are not being helped, they fail to proliferate. Thus, because the third level Th cells (T3) are not being activated by the idiotypic cascade, signals never percolate along "B-B-B" pathways in both models. Percolation is subsequently analysed in 200-D networks, comprised of random mixtures of "B-B" and "B-Th" pathways. As soon as the connectivity of the symmetric Th-B interactions exceeds a threshold level of two connections per clone, the idiotypic cascade percolates extensively in the ThId model. Conversely, due to the asymmetry, signals do not percolate at all in the MHC-restricted networks. Helper T cells thus set the conditions for idiotypic signal percolation. Firstly, considering "B-B" cell idiotypic interactions, it turns out to be essential to consider the activation of helper T cells (i.e. T3) for the anti-idiotypic B cells (B2). Secondly, due to the asymmetry, MHC-restricted Th and ThId cells differ with respect to the constitution of functional networks based on a "B-Th-B-Th" topology. MHC-restricted Th cells may altogether prevent the development of functional idiotypic interactions. Thus, idiotypic networks are not necessarily "unavoidable". http://www.sciencedirect.com/science/article/B6WMD-4KD4YD6-4/2/6026943ca16f1ecbb164b6284bdfdd91

Chem Codes: Chemical of Concern: PSM Rejection Code: VIRUS.

Bacteriophage of Lactococcus lactis ssp. lactis and ssp. cremoris, isolated in the United States and Argentina, were compared with respect to host range, adsorption, latent period, burst size and immunological cross-reactivity. Only 1 out of 13 U.S. culture isolates was sensitive to Argentinian phage. Argentinian L. lactis ssp. lactis C2 mutants were resistant to 13 U.S. phage isolates (4 prolate and 9 isometric). While Argentinian phage Stl-3 multiplied on U.S. culture isolate 59-1, low adsorption (38%) and insignificant burst size and latent period data were evident. Antisera prepared against U.S. phage D59-1 (prolate) and F4-1 (isometric) neutralized the lytic activities of all Argentinian prolate phage although the F4-1 antiserum was less effective. The data suggest homology especially between U.S. phage D59-1 and the Argentinian phage. Anal. aspects of the method were studied with a linear regression model, including the linearity of the responses, repeatability and detection limits, which ranged from 3 to 35 mg/L. The method of concn. used did not contribute to a noticeable loss of the chems., with recoveries of over 90%, except for fenthion. The method is applied to the anal. of 27 pesticides in groundwater, most of which are recovered at >70% efficiency which complies with the EPA criteria. Chem Codes: Chemical of Concern: PSM Rejection Code: CHEM METHODS.

This work presents a two-dimensional diffusional model to predict the simultaneous mass transfer and shrinkage during drying of solids with prolate spheroidal shape, considering that the changes in volume of solid are equal to the volume of evaporated water. The resulting equations are numerically solved, using the finite-volume method. This model was used to study numerically the effect of the air-drying conditions and shrinkage on the drying kinetic of banana peel for six experiments, considering the natural shape of this fruit. Here, it was treated as an ellipsoid of revolution. Several results are shown and analyzed such as the comparison between numerical and experimental data; the dimensionless shrinkage parameters; the relationships of length, superficial area and volume; the moisture content distribution and finally the mass transfer and diffusion coefficients. CAS Registry Numbers: 37205-54-2 (Phosphatidylinositol kinase); 73903-97-6 (Polyphosphoinositide phosphodiesterase) Role: BIOL (Biological study) (of human erythrocyte membranes, phosmetoxon effect on); 732-11-6 (Phosmet) Role: BIOL (Biological study) (phosmetoxon as metabolite of, toxicity of, to human erythrocyte, phosphoinositide phosphorylation and shape changes in relation to); 3735-33-9 (Phosmetoxon) Role: ADV (Adverse effect, including toxicity), BIOL (Biological study) (toxicity of, to human erythrocyte, phosphoinositide phosphorylation and shape changes during) In vitro incubation of red blood cells with phosmetoxon induced crenated and invaginated forms. [32P] phosphate incorporation was greater in membranes from erythrocytes exposed to 300 nM phosmetoxon for 10 min than in control cells. The highest incorporation was for phosphatidylinositol (PI), followed by phosphatidylinositol phosphate (PIP) and phosphatidylinositolbiphosphate (PIP2). An activation of phosphatidylinositol (PI) kinase was detected with 150 and 300 nM of the pesticide, while there was no change in polyphosphoinositides (PPI) phosphodiesterase activity. Results suggest an assocn. between changes in PI kinase activity, the phosphorylation cycle of phosphatidylinositols and alterations in erythrocyte morphol. induced by phosmetoxon. Citations: 14) Duke, C; Reconstructions of Solid Surfaces 1990 In the temp. range of 300-500 Deg, solid nanocryst. oxides react nearly stoichiometrically with numerous halocarbons, sulfur compds., and organophosphorus compds. In some cases, the reaction efficiencies can be improved by the presence of a small amt. of transition metal oxide as catalyst; for example, Fe2O3 on CaO and mobile intermediate species such as FeCl3 or Fe(SO3)x are important in the catalytic process. A series of environmentally problematic compds. are discussed herein, including CCl4, COS, CS2, C2Cl4, CHCl3, CH2Cl2, MeCl, and (MeO)2P(O)Me. Nanocrystals of CaO coated with a thin layer of Fe2O3 (or other transition metals) ==[Fe2O3]CaO, or intimately mixed ==Fe2O3/CaO were compared with pure CaO. It was found that (a) the presence of a small amt. of surface [Fe2O3] or other transition-metal oxide can have a marked effect on the destructive adsorption activity; (b) for some compds., such as CCl4, C2Cl4, SO2, and others, the nanocryst. CaO can react in stoichiometric amts., esp. if a transition metal oxide catalyst is present; (c) although the reaction with di-Me methylphosphonate is surface-limited, the nanocryst. calcium oxide performed well and at high capacity; (d) nanocryst. calcium oxide exhibits near stoichiometric activity with several interesting sulfur-contg. compds., such as COS and CS2; and (e) unfortunately, most fluorocarbons were not destructively adsorbed at 500 Deg under the conditions employed; however, some of these can be effectively mineralized over the calcium oxide at higher temps. These compds. include C2F6, C3F6, C2ClF3, and CHF3, and upon reaction, the surface areas decreased considerably, from about 100 to about 10 m2/g. The results of these expts. further demonstrate that, with the proper choice of catalytic material, some solid-gas reactions can be engineered to be rapid and essentially stoichiometric. Chem Codes: Chemical of Concern: PSM Rejection Code: FATE.

ABSTRACT: PESTAB. Northern Guam farms were surveyed in 1976 and 1977 for pesticide and fertilizer usage. The major pesticides used in 1976 and 1977 were Sevin (carbaryl), diazinon, malathion, Dibrom (naled). Kelthane (dicofol) was widely used in 1976 but not in 1977. Animal manure, 15-15-15 and 16-16-16 were the most widely used fertilizers in 1976 and 1977. A notable increase in the use of ammonium sulfate occurred in 1977. The chance of groundwater contamination from agricultural chemicals is minimal since a very small percentage of the land area is currently being utilized for full-time farming. Bench scale lysimeter studies were conducted to determine the concentrations of nitrogen and phosphorus in percolate water after passing the root zone of selected fertilized vegetables. Tomatoes, Chinese cabbage, head cabbage, eggplant, and bell pepper were grown using ammonium sulfate, chicken manure, potassium nitrate, and 15-15-15 as fertilizers. Potassium nitrate is the best nitrogen source but is cost prohibitive and 15-15-15 percolates excessive amounts of nitrate and ammonia nitrogen. Actively growing vegetables used the nitrogen in the ammonium sulfate and chicken manure at comparable rates. (Author abstract by permission)

Chem Codes: Chemical of Concern: PSM Rejection Code: BACTERIA.

A plasmid-encoded phage abortive infection mechanism (AbiL) was identified from Lactococcus lactis biovar. diacetylactis LD10-1. AbiL conferred complete resistance to the small isometric-headed phage [phi]712 (936 species) and partial resistance to the prolate-headed phage [phi]c2 (c2 species) when introduced into L. lactis LM0230. However, AbiL was not effective against the small isometric-headed phage ul36 (P335 species). The AbiL determinant was sequenced and it consists of two open reading frames, abiLi and abiLii. Their encoded proteins did not share significant homology with any known proteins in the protein databases. Transcriptional analysis indicated that abiLi and abiLii are organized as a single operon. Deletion within abiLii abolished the phage resistance. The levels of four [phi]c2-specific transcripts, three within the early transcribed region and one within the late transcribed region, were examined by RT-PCR, no effect of AbiL on synthesis of these transcripts was detected, suggesting that AbiL may act at a point after the transcription of [phi]c2 in L. lactis. Abstract: Pollen of Platanus was studied using light (LM) and electron microscopy (SEM and TEM). Overall, pollen is uniform in modern Platanus (small, tricolpate, prolate to spheroidal, reticulate, semitectate). A number of characters, however, display remarkable variability within a taxon and even a single anther (size; foveo-reticulate, fine to coarse reticulate ornamentation). Platanus kerrii (subgenus Castaneophyllum) differs from the remaining species by its high and "folded" reticulum and possibly the smooth colpus membrane. Moreover, to our knowledge, pollen of the P. kerrii - type is not known from the fossil record. The exine in modern and fossil Platanaceae shows great structural similarity, but the thickness of the foot layer within the ectexine is less variable and normally smaller in modern taxa. Furthermore, in Early Cretaceous to Early Cainozoic Platanaceae a number of distinct pollen types occurred that are not known within the modern Platanus. Considering pollen of Platanaceae from the Early Cretaceous to today, a dynamic picture of the evolution of the family emerges. In the first phase (Early Cretaceous) pollen of extinct genera such as Aquia differed considerably from modern Platanus and shows strong similarity to basal eudicot taxa such as Ranunculales (e.g. Lardizabalaceae). The Late Cretaceous Platananthus hueberi displays a distinct coarse reticulum that is unknown from modern Platanus but similar to some taxa of Hamamelidaceae (e.g. Exbucklandia). After the first phase of eudicot radiation that appears to have been characterized by strongly reticulate evolution, platanaceous diversity decreased in the course of the Cainozoic. Despite this, the pollen type of the modern subgenus Castaneophyllum (P. kerrii type) seems to be an innovation that originated after the initial radiation of the family. (SPE) cartridges contg. C18 sorbent materials and their anal. by liq. chromatog. with UV detection. The effects of temp. and matrix type on the recovery of these contaminants in cartridges for a period of 1 mo were studied. Three storage temps., 20, 4 and -20 DegC and three storage periods, 3, 7 and 30 days, were considered. Complete recovery for all the compds. was obsd. in C18 cartridge kept at -20 DegC for one month. The type of matrix water selected appears to have a significant influence on the stability of the target pesticides stored on cartridges, compared to the Milli-Q water. The stability of the pesticides was also examd. in bottled surface water, in order to compare it to their stability in SPE cartridges and to evaluate the pretreatment of the aq. matrix with two stabilizers. The addn. of $Na_2S_2O_3$ to the water sample, compared to the $HgCl_2$ is effective to increase the stability of organophosphorus pesticides. descriptors encoding lipophilicity (H0 to H5) and the H-bonding acceptor ability (HBA0) and H-bonding donor ability (HBD0) of the pesticides. A three-layer feedforward neural network trained by the back-propagation algorithm was used as statistical engine for deriving a powerful QSAR model accounting for the wt. of the fish, time of exposure, temp., pH, and water hardness. Citations: 40) Lipnick, R; QSAR in Environmental Toxicology-IV 1991, 131 Quant. structure-toxicity relationship (QSTR) models were derived for estg. the acute oral toxicity of organophosphorus pesticides to male and female rats. The 51 chems. of the training set and the nine compds. of the external testing set were described by means of autocorrelation vectors encoding lipophilicity, molar refractivity, H-bonding acceptor ability (HBA) and H-bonding donor ability (HBD) of the mols. A feature selection was employed for selecting the most relevant autocorrelation descriptors. A PLS regression anal. and an artificial neural network (ANN) were used for deriving models accounting for the sex of the organisms in the estn. of the toxicity of pesticides. The best results were obtained with an 8/4/1 ANN model trained with the back-propagation and conjugate gradient descent algorithms. The root mean square residual (RMSR) values for the training set and the external testing set equaled 0.29 and 0.26, resp. Structure-Activity Relationship (QSAR) model was derived for estg. the acute toxicity of pesticides against Oncorhynchus mykiss under varying exptl. conditions. Chems. were described by means of autocorrelation descriptors encoding lipophilicity (H0 to H5) and the H-bonding acceptor ability (HBA0) and H-bonding donor ability (HBD0) of the pesticides. A three-layer feed forward neural network trained by the back-propagation algorithm was used as statistical engine for deriving a powerful QSAR model accounting for the wt. of the fish, time of exposure, temp., pH, and hardness. Citations: Zakarya, D; SAR QSAR Environ Res 1997, 6, 183 The ability of partial least square (PLS) regression anal. to derive a quant.-structure activity relationship (QSAR) model integrating both types of variables was compared with artificial neural network (ANN). PLS regression anal. is a very powerful statistical technique for deriving classical QSAR models to predict the toxicity of chems. from their physicochem. properties and/or topol. indexes. These models are derived from toxicity results obtained in very specific exptl. conditions. However, in aquatic toxicol., the correct hazard assessment of xenobiotics requires to simulate the ecotoxicol. behavior of chems. under various conditions of temp., pH, hardness, and so on. The study shows that these exptl. parameters cannot be integrated as variables in PLS models to increase their flexibility. Conversely, the ANNs do not have this limitation and their introduction allows to derive very flexible environmental QSAR models. 326. Dewulf, W., Jancsok, P., Nicolai, B., De Roeck, G., and Briassoulis, D. (1999). Determining the Firmness of a Pear using Finite Element Modal Analysis. *Journal of Agricultural Engineering Research* 74: 217-224.
Chem Codes: Chemical of Concern: PSM Rejection Code: CHEM METHODS.

In this paper, the variation of the dynamic characteristics of a pear (Conference type) due to changes in material characteristics is investigated using finite element simulations. An image processing techniques has been used to obtain the geometrical model of a Conference pear. The dynamic behaviour of this type of pear and the correlation of its behaviour with material characteristics has been investigated by using a numerical modal analysis. From these results, it was concluded that the Young's modulus of the spherical calyx end of the pear could be determined from the oblate-prolate modes and that the Young's modulus of the stem end of the pear could be determined from the first bending modes. The firmness of the spherical calyx end of the pear can be determined analogous to a spherical fruit. A finite element analysis using a conical model for the stem end of the pear indicated that a similar formula for the firmness of the stem end of the pear can be derived. http://www.sciencedirect.com/science/article/B6WH1-45GMGDS-F/2/7d063fa92514f334d3c4b516a3611964

human consumption 1980, 80/778/EEC Currently, no guidelines cover use of pesticides in the forested areas of the Canary island of Tenerife. An index-based model (Li) was used to rank the leaching potential of 50 pesticides that are, or could be, used for management purposes in the pine forest areas of Tenerife. Once the pesticides with the greatest leaching potential were identified, regional-scale groundwater vulnerability assessments, with consideration for data uncertainties, were generated using soil, climatic, and chem. information in a geog. information system framework for all pine forest areas of the island. Process-based simulations with the pesticide root zone model for the areas and pesticides of highest vulnerability were conducted to quant. characterize the leaching potentials. Carbofuran, hexazinone, picloram, tebuthiuron, and triclopyr were each identified as being potential leachers. CAS Registry Numbers: 52-85-7; 56-38-2; 56-72-4; 78-34-2; 86-50-0; 115-90-2; 121-75-5; 298-02-2; 330-55-2; 563-12-2; 732-11-6; 950-37-8; 2104-64-5; 2310-17-0; 2642-71-9; 3383-96-8; 10606-46-9; 13194-48-4; 21609-90-5; 23505-41-1 Role: ANT (Analyte), ANST (Analytical study) (detn. of, by HPLC with on-line photolysis-electrochem. detection) Org. thiophosphate agricultural chems., such as malathion [121-75-5], parathion [56-38-2], and others, were analyzed by high-performance liq. chromatog. (HPLC) with on-line photolysis (hv), followed by electrochem. detection (EC) using single or dual-electrode approaches for the species generated. This approach (HPLC-hv-EC) was applied to different thiophosphates, most of which are widely used agriculturally and for which trace residue levels are routinely monitored. Dual electrode response ratios were detd. for all of these analytes, along with min. detection limits in many cases. These approaches can also be used for the quality control evaluation of com. formulations by flow injection anal. with hv-EC and no HPLC sepns. Wheat middling exts. were analyzed by the commonly used gas chromatog. flame photometric detection method of residue anal., as well as by HPLC-hv-EC. These comparative studies indicate that the newer method is reproducible, accurate, precise, and entirely reliable. Std. addns. were applied to wheat middling exts., and the quant. results are compared with the external std. method. [on SciFinder (R)] 0021-8561 organothiophosphate/ pesticide/ analysis/ HPLC

329. Dismukes, G. Charles, Frank, Harry A., Friesner, Richard, and Sauer, Kenneth (1984). Electronic interactions between iron and the bound semiquinones in bacterial photosynthesis. EPR spectroscopy of oriented cells of Rhodopseudomonas viridis. *Biochimica et Biophysica Acta (BBA) - Bioenergetics* 764: 253-271.
Chem Codes: Chemical of Concern: PSM Rejection Code: BACTERIA.

Electron paramagnetic resonance (EPR) spectroscopy of the iron-semiquinone complex in photosynthetic bacterial cells and chromatophores of Rhodopseudomonas viridis is reported. Magnetic fields are used to orient the prolate ellipsoidal-shaped cells which possess a highly ordered internal structure, consisting of concentric, nearly cylindrical membranes. The field-

oriented suspension of cells exhibits a highly dichroic EPR signal for the iron-semiquinone complex, showing that the iron possesses a low-symmetry ligand field and exists in a preferred orientation within the native reaction-center membrane complex. The EPR spectrum is analyzed utilizing a spin hamiltonian formalism to extract physical information describing the electronic structure of the iron and the nature of its interaction with the semiquinones. Exact numerical solutions and analytical expressions for the transition frequencies and intensities derived from a perturbation theory expansion are presented, and a computer-simulated spectrum is given. It has been found that, for a model which assumes no preferred orientation within the plane of the membranes, the orientation of the Fe2+ ligand axis of largest zero-field splitting (Z, the principal magnetic axis) is titled 64+/-6[degree sign] from the membrane normal. The ligand field for Fe2+ has low symmetry, with zero-field splitting parameters of D1=7.0+/-1.3 cm-1 and E1=1.7+/-0.5 cm-1 and E1/D1=0.26 for the redox state Q1-Fe2+Q2-. The rhombic character of the ligand field is increased in the redox state Q1Fe2+Q-2, where 0.33>E2/D2>0.26. This indicates that the redox state of the quinones can influence the ligand field symmetry and splitting of the Fe2+. There exists an electron-spin exchange interaction between Fe2+ and Q-1 and Q-2, having magnitudes J1=0.12+/-0.03 cm-1 and J2[reverse similar, equals]0.06 cm-1, respectively. Such weak interactions indicate that a proper electronic picture of the complex is as a pair of immobilized semiquinone radicals having very little orbital overlap (probably fostered by superexchange) with the Fe2+ orbitals. The exchange interaction is analyzed by comparison with model systems of paramagnetic metals and free radicals to indicate an absence of direct coordination between Fe2+ and Q-1 and Q-2. Selective line-broadening of some of the EPR transitions, involving Q- coupling to the magnetic sublevels of the Fe2+ ground state, is interpreted as arising from an electron-electron dipolar interaction. Analysis of this line-broadening indicates a distance of 6.2-7.8 A between Fe2+ and Q-1, thus placing Q1 outside the immediate coordination shell of Fe2+.

Citations: 26) Wania, F; Environ Sci Technol 2003, 37, 1352 Air samples were collected in an urban area (central Strasbourg, France) in spring/summer 2004, to det. concns. of different pesticides in gaseous and particulate phases and compare the efficiency of adsorbents at trapping the gaseous phase. Two high-vol. samplers were placed next to each other in the botanical garden in Strasbourg. Air was sampled for 48-h using a glass fiber filter and different adsorbents. These adsorbents and adsorbent combinations were compared: XAD-2 with polyurethane foam (PUF), XAD4 with PUF, XAD-2 with a PUF-XAD2-PUF sandwich, and PUF with a PUF-XAD4-PUF sandwich. In the order of efficiency at trapping pesticides, sandwiches were most efficient, followed by XAD-2 and XAD-4 resins; however, although the sandwiches were slightly better at trapping than XAD-2, use of XAD-2 is recommended for tech. reasons. PUF were least efficient at trapping. Among 27 pesticides analyzed, trifluralin, alachlor, metolachlor, and captan were the most concd., followed by lindane, a-endosulfan and diflufenican. This result was in accordance with farming activity in the Alsace region, where pesticides used on large crops (maize, cereals) are applied in the greatest quantity. Vineyards are another important form of agriculture in Alsace, but the quantity of pesticides applied vs. those used on large crops is very low, explaining the low detection of vineyard pesticides in air obsd. here. Concns. depended on the pesticide and its properties; on the whole, they remained rather low. It is important to conduct these

measurements in urban environments, since these compds. can be harmful to human health and the environment; thus, their concns. must be monitored. The mols. were described by means of the frequency of 17 structural fragments. Before training the NN, different scaling transformations were assayed. Best results were obtained with correspondence factor anal. which also allowed a redn. of

dimensionality. The training and testing sets of the NN anal. gave 95.5% and 84.6% of good classifications, resp. Comparison with discriminant factor anal. showed that a backpropagation NN was more appropriate to model the field half-lives of pesticides. (PCA). Classical PCA displays underline structure-property relationships. However, interpretation of PCA requires ref. to the original data matrix and comparisons made between every point. To overcome this problem, a novel graphical approach, based on collections of maps encoding the chem. and structural information included in the original data set, was used to interpret the results. Multivariate analyses coupled to graphical tools were useful for interpreting physicochem. properties of pesticides in terms of multivariate structure-property relationships (MSPR). Members of the following chem. classes were analyzed: organophosphorus, organochlorine, phenol, triazine, uracil, phenoxy acid, urea, carboxylic acid, amide, and others including amines, organometallics, esters, and heterocycles. Values for the heat of fusion, exptl. temp. onset, theor. temp. onset for 100% pure compd., and percent purity are presented. DSC was applicable to most classes of org. environmental stds. and their metabolites. [on SciFinder (R)] 0040-6031 DSC/ environmental/ std/ purity;/ fusion/ heat/ environmental/ std/ DSC

Sufficient selectivity was achieved to allow generic sample clean up even for very complex food matrixes. In particular, the Waters Micromass Quattro micro GC can be used in routine anal. at 10 ms dwell times. Subsequent expansion of this method to include an increased no. of MRM transitions would be possible without loss in sensitivity. The system provided good sensitivity (1-10 pg on column) for the majority of pesticide residues, allowing the amt. of matrix introduced into the GC system to be minimized. Chem Codes: Chemical of Concern: PSM Rejection Code: MODELING.

ABSTRACT: BIOSIS COPYRIGHT: BIOL ABS. The toxicity data of pesticides were summarized and compared amongst different animal species and types of bioassays. These comparisons showed the expected inter-species and inter-bioassay variability. After quantitative and statistical analysis of these data, it was concluded that, on the average, a 2-year dog bioassay detected toxic responses at similar doses as a 2-year rat study, and that both of these bioasays detected toxic responses at lower doses than either a rat 2-generation bioassay, a rat developmental toxicity study, or a 2-year mouse bioassay. Although these chronic dog and rat bioassays were found to detect toxic responses at lower doses than the other studies listed, this analysis does not reflect the seriousness of the effects that were compared. Within the confines of this analysis, then, it appears that a 2-year dog and rat study, reproductive and developmental bioassays are a sufficient data base on which to estimate high confidence Reference Doses (

Chem Codes: Chemical of Concern: PSM Rejection Code: HUMAN HEALTH.

ABSTRACT: BIOSIS COPYRIGHT: BIOL ABS. Two sets of 65 risk/safety assessments are compared. These assessments, mostly for pesticide chemicals, were developed by the World Health Organization (WHO) and the U.S. Environmental Protection Agency (EPA) at different times, often with different toxicity data, and with slightly different methods. Despite these differences, 38 sets of assessments give values that are within a 3-fold range of each other; 18 of these 38 are essentially identical (when rounded to one digit of precision), although not always for the same reasons. An additional 20 sets give values that lie within a 30-fold range; 6 sets lie within

a 300-fold range; and the bromomethane ADI and RfD are 700-fold apart. In addition, on average the EPA values are lower than the WHO numbers. These comparisons are discussed in relationship to a developing world-wide consensus that the methods for evaluating the safety/risks from various chemicals should be more consistent and the resulting assessments should be

Drought or excessive rainfall may seriously affect dissipation rates, routes, and the extent of movement through soil profiles. The pesticide root zone model (PRZM) is designed to predict pesticide movement in unsatd. soils within and below the plant root zone in agricultural systems. The applicability of this model to a forested watershed was tested by using on site hydrol. data to simulate a field application of lindane. PRZM-predicted data were compared with measured residue levels and found to est. accurately lindane movement and leaching at shallow soil depths (0-10 cm), but underestimated residue levels at deeper soil depths (40-50 cm). Model simulations were used to evaluate various insecticide and herbicide

application scenarios used in pine plantation management. Results from these simulations indicate that insecticides commonly used for gypsy moth (Lymantria dispar L.) or southern pine beetle (Dendroctonus frontalis Zimm.) control either are not sufficiently persistent or are adsorbed in the soil to such an extent that they do not pose a potential groundwater contamination problem. In contrast, site prepn. herbicides show a potential to leach whenever proper meterol. conditions such as rainfall prevail after application. These herbicides are persistent (t1/2 > 50), moderately adsorbed (10 > Kd > 0.1, assuming 1.7% org. matter), and applied under conditions of reduced evapotranspiration. A large no. of steric, phys. and electronic descriptors have been calcd. After the removal of descriptors that were highly cross-correlated or correlated poorly with activity, the genetic algorithm was employed to select the optimum descriptors for use in multivariate regression. Best equation r2 and rcv2 values were 0.943 and 0.905 resp. Mol. field Anal. was also used in conjunction with the Genetic Function Approxn. (GFA) algorithm to obtain predictive equations, r2 and rcv2 values were 0.939 and 0.896 resp. However, when the data were randomized, results proved to be as good, (and in one case better) than using the correct exptl. values. For equations subsequently derived using the Genetic Partial Least Squares (G/PLS) technique (best r2 and rcv2 values being 0.943, 0.905 resp.), randomization gave worse answers than using the correct exptl. values. This work demonstrates the danger of using the powerful GFA technique to select from a large no. of parameters, but establishes that the G/PLS method is sufficiently robust to provide reliable results. 343. Drewes, J. E., Fox, P., and Nellor, M. H. (Efficiency and Sustainability of Soil-Aquifer Treatment for Indirect Potable Reuse of Reclaimed Water. *Schriftenr ver wasser boden lufthyg. 2000; 105:227-32. [Schriftenreihe des vereins fur wasser-, boden- und lufthygiene]: Schriftenr Ver Wasser Boden Lufthyg*.
Chem Codes: Chemical of Concern: PSM Rejection Code: CHEM METHODS, HUMAN HEALTH.

ABSTRACT: An increasing number of municipalities are considering the indirect reuse of treated wastewater (recycled water) by groundwater recharge as a feasible option to augment potable water supplies. This planned approach offers several advantages compared to the conventional way of discharging effluents into surface waters, including the additional treatment afforded as the water percolates and co-mingles with groundwater (soil aquifer treatment). While groundwater recharge has been used in the United States (U.S.) for several decades and has been the subject of a number of studies, limitations in methodology and testing have prevented many within the

scientific and technical community from being able to fully address a number of complex public health questions related to organic chemicals, nitrogen and microorganisms. Ongoing research being conducted in Arizona and California is directed at reducing the uncertainties about the efficiency and sustainability of soil aquifer treatment for indirect potable reuse of recycled water.

Index Terms: Pesticides (organophosphorus; solid phase extn. of organophosphorus pesticides from tap and surface water with capillary gas chromatog.); Environmental pollution (pesticide; detn. of organophosphorus pesticides in Tunisian surface and tap water by solid phase extn. and capillary gas chromatog.); Drinking waters; River waters (solid phase extn. of organophosphorus pesticides from water with C-18 bonded silica and subsequent capillary gas chromatog.); Extraction (solid-phase; solid phase extn. of organophosphorus pesticides from tap and surface water with C-18 bonded silica and subsequent capillary gas chromatog.)
CAS Registry Numbers: 7631-86-9 (Silica) Role: ARU (Analytical role, unclassified), ANST (Analytical study) (C-18 bonded; solid phase extn. of organophosphorus pesticides from water with C-18 bonded silica and subsequent capillary gas chromatog.); 55-38-9 (Fenthion); 56-38-2 (Parathion-ethyl); 56-72-4 (Coumaphos); 60-51-5 (Dimethoate); 62-73-7 (Dichlorvos); 86-50-0 (Azinphos-methyl); 121-75-5 (Malathion); 122-14-5 (Fenitrothion); 298-00-0 (Parathion-methyl); 298-02-2 (Phorate); 298-04-4 (Disulfoton); 311-45-5; 333-41-5 (Diazinon); 563-12-2 (Ethion); 732-11-6 (Phosmet); 2642-71-9 (Azinphos-ethyl) Role: ANT (Analyte), POL (Pollutant), ANST (Analytical study), OCCU (Occurrence) (detn. in drinking and surface water by solid phase extn. with C-18 bonded silica and capillary gas chromatog.); 7732-18-5 (Water) Role: AMX (Analytical matrix), ANST (Analytical study) (solid phase extn. of organophosphorus pesticides from water using capillary gas chromatog.) The extn. and enrichment of 16 organophosphorus pesticides (OPPs) were studied in Tunisian surface and tap waters as a part of fast and reliable method for monitoring these pesticides. This extn. was performed using C-18 bonded silica cartridges. Recovery depends on the polarity of elution solvent, pesticide levels, and the treated water vol. For a 250 mL vol. of spiked water at 0.4 mg/L, the recovery of the OPPs was 70-98% but dimethoate recovery was 52-60%. The limits of detection are 0.007-0.03 mg/L. The chromatog. behavior (resoln., relative retention etc.) of these pesticides on non polar CC (HP-101), slightly polar CC (SPB-5) and intermediate polar CC (SPB-608 and HP-1701) is discussed. Applications are reported for the detn. of parathion-Et and parathion-Me in Medjerda River. [on SciFinder (R)]

345. Driss, M. R., Hennion, M. C., and Bouguerra, M. L. (1993). Determination of Carbaryl and Some Organophosphorus Pesticides in Drinking Water Using on-Line Liquid Chromatographic Preconcentration Techniques. *J chromatogr* 639: 352-358.
Chem Codes: Chemical of Concern: PSM Rejection Code: CHEM METHODS.

ABSTRACT: BIOSIS COPYRIGHT: BIOL ABS. Reversed-phase high-performance liquid chromatography (HPLC) was adapted for the determination of trace concentrations of carbaryl and seven organophosphorus pesticides in drinking water. Between 100 and 300 ml of water sample is passed through a 1.5-cm precolumn, packed with C18-bonded silica or styrene-divinylbenzene copolymer (PRP-1) sorbent at a flow-rate of 3 ml/min. The HPLC system is then switched to an acetonitrile-water gradient elution programme. The analytes that have been concentrated on the precolumn are eluted and separated on a 15-cm C18 analytical column and are determined by measuring their UV absorption at 254 nm. This wavelength was selected as the optimum for the simultaneous determination of these pesticides. The preconcentration yields of the examined solutes obtained with the two types of precolumn are almost identical. Band broadening is avoided by a suitable choice of the C18 precolumn and the analytical column. With 200 ml of tap water, the rec

347. Dunbabin, J. S. and Bowmer, K. H. (1992). Potential Use of Constructed Wetlands for Treatment of Industrial Wastewaters Containing Metals. *Sci total environ* 111: 151-168.
Chem Codes: Chemical of Concern: PSM Rejection Code: FATE.

ABSTRACT: BIOSIS COPYRIGHT: BIOL ABS. Natural wetlands are effective sinks for metals. Processes of metal removal and mobilisation include sedimentation, adsorption, complexation, uptake by plants, and microbially-mediated reactions including oxidation and reduction. Recently, wetlands for wastewater purification have been constructed for treatment of sewage and urban runoff, and also show good potential for concentrating metals from industrial wastewaters and mine seepage. Constructed wetlands include open water pond-like systems, usually sediment-lined, containing floating, submerged and emergent plants. Another design is

based on the use of permeable substrata such as gravel commonly planted with emergent wetland plants such as Typha, Schoenoplectus, Phragmites or Cyperus. The wastewater percolates through the gravel, giving better access to the plant roots and rhizomes and exposure to oxygenated conditions in the rhizosphere. Hydraulic design appears to be critical to the performance of these systems, w

Citations: Anon; US EPA's Reregistration Eligibility Decision (RED) documents, http://www.epa.gov/pesticides/reregistration/ 2003 Establishing priorities for regulatory and scientific assessments of pesticides is difficult given the large no. of registered pesticide products and varied use patterns of each product. According to the general paradigm of \"Risk = Toxicity * Exposure\", a relative risk ranking of agricultural pesticides was developed using a modified Chem. Hazard and Evaluation for Management Strategies (CHEMS) model. Release-weighting factors were derived using pesticide sales information. Factors for each active in each media were detd. on a scale of 1 to 10 relative to the largest pesticide release in each resp. media. A risk score was then tabulated by multiplying the sum of release-weighted toxicity endpoints (i.e. acute oral LD50, acute inhalation LC50, carcinogenicity rating, no obsd. adverse affect level, acute fish LC50, acute Daphnia EC50) by the sum of weighted exposure factors (i.e. soil half-life, log BCF). While the model makes use of toxicity and exposure data, the risk ranking produced does not represent a risk assessment. Rather, the results from CHEMS should be viewed as a quant. risk

ranking used to prioritize substances for future risk assessment and management activities. Hazard and exposure data were collected for a subset of 31 active ingredients, representing 94% of Prince Edward Island's 2001 pesticide sales by mass. According to the resultant risk scores, the highest ranked substances were chlorothalonil, diquat dibromide, mancozeb, metiram, and carbofuran. Limitations included the use of pesticide sales data as a proxy for release and the reliance on modeled data for log BCF and detg. environmental partitioning. In spite of its limitations, the CHEMS risk ranking scheme provides a useful tool for prioritizing pesticides of concern, for future action. 349. Durig, J. R., Sullivan, J. F., Little, T. S., and Cradock, Stephen (1984). Low resolution microwave, infrared and Raman spectra, conformational stability, and vibrational assignment of isopropylisothiocyanate. *Journal of Molecular Structure* 118: 103-117.
Chem Codes: Chemical of Concern: PSM Rejection Code: CHEM METHODS.

The low resolution microwave spectrum of isopropylisothiocyanate, (CH32CHNCS, has been recorded from 18.0 to 39.0 GHz. From the spacing of the central transitions for the near prolate symmetric top it is shown that the value of 2490 MHz for B+C is consistent with the skew conformer with a C---N=C angle of [approximate] 145[degree sign] where the NCS moiety is eclipsing one of the methyl groups, although the trans conformer where the lone pair of electrons on the nitrogen is eclipsing the hydrogen atom cannot be completely ruled out. The infrared and Raman (3200--30 cm-1 spectra of gaseous and solid isopropylisothiocyanate have been recorded. Also, the infrared spectrum of the sample isolated in a nitrogen matrix at 10 K has been recorded from 3200 to 300 cm-1. Additionally, the Raman spectrum of the liquid has been obtained and qualitative depolarization values measured. Based on a comparison of the vibrational data for the fluid and solid phases it has been determined that there is little evidence for the presence of a second conformer at ambient temperature and there was no evidence for the presence of two conformers in the matrix isolated sample. A complete vibrational analysis, based on infrared band contours, depolarization values and group frequencies, is proposed. The two methyl torsions were observed in the Raman spectrum of the solid at 285 and 250 cm-1 and from these data the barrier to internal rotation was calculated to be 1640 cm-1 (4.69 kcal mol-1). Additionally, a very weak B-type band centered at [approximate]45 cm-1 was observed in the infrared spectrum of the gas which probably arises from the asymmetric torsion of the NCS moiety. These results are compared to similar quantities for some corresponding molecules.

350. Dutta, S. K., Nema, V. K., and Bhardwaj, R. K. (1988). Physical properties of gram. *Journal of Agricultural Engineering Research* 39: 259-268.
Chem Codes: Chemical of Concern: PSM Rejection Code: NO TOX DATA.

The dependence of physical properties of gram on moisture content was determined. The best approximate shape was found to be a prolate spheroid. At 10[middle dot]9% moisture content d.b., the measurements yielded an average 1000 grain weight of 0[middle dot]173 kg, a mean surface area of 133[middle dot]4 mm2, and sphericity and roundness of 74% and 70% respectively. In the moisture range from 9[middle dot]64 to 31[middle dot]0% d.b., studies on rewetted gram showed that the bulk density changed from 780 to 708 kg/m3, kernel density from 1311 to 1257 kg/m3; porosity from 40[middle dot]5 to 43[middle dot]7% and static coefficient of friction from 0[middle dot]384 to 0[middle dot]651 over surfaces of different materials. The angle of repose was observed to change from 25[middle dot]5[degree sign] to 30[middle dot]4[degree sign] in the moisture range from 8[middle dot]62 to 17[middle dot]6% d.b.

351. Earnshaw, W. C., King, J., Harrison, S. C., and Eiserling, F. A. (1978). The structural organization of DNA packaged within the heads of T4 wild-type, isometric and giant bacteriophages. *Cell* 14: 559-568.

Chem Codes: Chemical of Concern: PSM Rejection Code: VIRUS.

We present electron microscopic and X-ray diffraction evidence concerning the structural organization of condensed DNA within a series of T4 bacteriophage with the following head morphologies: prolate (wild-type), isometric and giant (with greatly increased axial ratio). In all cases, the DNA helix segments are locally parallel and 27 A apart. For the giant particles, we show that the DNA forms a large coil whose axis is perpendicular to the axis of the phage tail. This evidence, combined with previous results from a series of isometric bacteriophages (), leads to a model for the organization of condensed DNA that may apply to most dsDNA-containing bacteriophages. http://www.sciencedirect.com/science/article/B6WSN-4C7WBN8-D/2/4a5a140622308b4d3fb1f9b3ed0a05b7

352. Earnshaw, William C., King, Jonathan, and Eiserling, Frederick A. (1978). The size of the bacteriophage T4 head in solution with comments about the dimension of virus particles as visualized by electron microscopy. *Journal of Molecular Biology* 122: 247-253.
Chem Codes: Chemical of Concern: PSM Rejection Code: BACTERIA.

We report X-ray diffraction results permitting calculation of the radius of the bacteriophage T4 head in solution. Isometric headed mutant particles, consisting of the two hemispherical caps of wild-type T4, were found to be spheres of radius 425 A. Giant headed particles, an amplification of the extra capsomeres which give the T4 head its prolate shape, were found to be cylinders of radius 427 A. We use these and other small-angle X-ray diffraction results in a quantitative discussion of the distortion artefacts caused by a number of electron microscope specimen preparation techniques. http://www.sciencedirect.com/science/article/B6WK7-4DMP383-D/2/56242189fcb08c7cfb8722d233633276

Chem Codes: Chemical of Concern: PSM Rejection Code: FATE, CHEM METHODS.

ABSTRACT: BIOSIS COPYRIGHT: BIOL ABS. Ozonation may alter the functional group composition, molecular weight (MW), and behavior of natural organic matter (NOM) in reactions of significance for drinking water treatment. In this work, the transformation of NOM by ozone was monitored by acid-base titrations, ion chromatography, and gel-permeation chromatography (GPC). The results led to an improved understanding of how ozonation affects NOM and how ozonated NOM affects the solubility of freshly precipitated iron and aluminum hydroxides. Organic acidity increased substantially during ozonation, and most of the newly produced organic acid groups were ionized at pH 4.0. Of 27 simple organic acids assayed in ozonated NOM, oxalic acid was dominant. The concentration of oxalate produced upon ozonation increased with ozone dose, solution pH, and Fe(II) concentration. Ozonation of NOM destroyed compounds of high and low apparent MW as determined by GPC and increased the concentration of compounds with intermediate appa

356. Edwards, W. M. and Glass, B. L. (1971). Methoxychlor and 2,4,5-T in Lysimeter Percolation and Runoff Water. *Bull. Environ. Contam. Toxicol. Vol. 6, no. 1, pp. 81-84. 1971.*
Chem Codes: Chemical of Concern: PSM Rejection Code: FATE.

Abstract: Trichlorophenoxyacetic acid (2,4,5-T), a biodegradeable chlorinated hydrocarbon herbicide and Methoxychlor (2,2-bis(p-methoxyphenyl)-1,1,1-trichloroethane) an insecticide, were used in percolation and runoff studies from a field lysimeter at the North Appalachian Experimental Watershed, Coshocton, Ohio. The predominant cover crops were poverty grass and broad leafed weeds growing on silt loam over sandstone bedrock. Runoff and percolation were monitored for 14 months following an application of 11.2 kg/ha 2,4,5-T and 22.4 kg/ha Methoxychlor. Runoff during the test period carried 0.05 percent of the applied 2,4,5-T with half the loss occurring within 32 days. More than 25 percent of the total loss occurred in storm water 21 days after application when the conc reached 380 mu g/litre. Total Methoxychlor removed by runoff was 0.004 percent of the application with low removal rates during the 1st 3 months. Percolate water intercepted at a depth of 2.44 m contained no Methoxychlor but trace amounts of 2,4,5-T.

ABSTRACT: BIOSIS COPYRIGHT: BIOL ABS. The influence of different NH4+ loads on aluminium speciation in percolating water was studied on acid luvisols with similar soil-pH values but with different soil adsorption surface characteristics. All of the applied NH4+ was nitrified and therefore led to proton production. Thus, Al displacement in the percolate was increased. The extent of this enhanced translocation was found to be chiefly a function of the amount of exchangeable base cations which buffered the protons produced by nitrification. The proportion of the different Al species in the percolate was altered at large NH4+ loads. Very large Al3+ concentrations eliminated Al species bound to dissolved organic matter and particles, presumably because of flocculation and precipitation of organic ligands. Furthermore, increased NO3- and Al3+ concentrations enhanced the desorption of F- giving rise to an additional increase in Al displacement by the formation of Al fluoro complexes in the aqueous phase.

Study. *Water environ res. 2005 jul-aug; 77(4):425-8. [Water environment research : a research publication of the water environment federation]: Water Environ Res.*
Chem Codes: Chemical of Concern: PSM Rejection Code: FATE, BACTERIA.

ABSTRACT: When ferrochromium is produced at Vargön Alloys AB (Vargön, Sweden), an offgas dust is generated as a byproduct. A leachate that contains hexavalent chromium (Cr6+) is formed when rainwater percolates through the dust deposit. In this study, Cr6+ in the leachate was reduced to trivalent chromium (Cr3+) by biological treatment in a biofilm process operated under anaerobic conditions. The reactor volume was 26 m3 and it was filled with 16 m3 plastic packing. Acetic acid was added as an electron donor. The Cr6+ was reduced from 10 to 20 mg/L to below 0.03 mg/L when the reactor was operated at a hydraulic retention time of 11 hours. The reduction activity in the process gradually decreased as the water temperature dropped below 10 degrees C.

359. El Gharmali, A., Rada, A., El Adnani, M., Tahlil, N., El Meray, M., and Nejmeddine, A. ([Impact of Acid Mining Drainage on the Quality of Superficial Waters and Sediments in the Marrakesh Region, Morocco]. *Environ technol. 2004, dec; 25(12):1431-42. [Environmental technology]: Environ Technol.*
Chem Codes: Chemical of Concern: PSM Rejection Code: FATE.

ABSTRACT: The aim of the present study is the evaluation of the effects of the acid drainage of three abandoned mining sites: SB-Othmane, Kettara and Draâ-sfar, on water and sediment quality of the Tensift River and its two temporary tributaries, the Kettara and El-Coudia Oueds. These mining sites located near Marrakesh contain mining residues abandoned for ten to twenty years. They are presently in an agricultural region of the Haouz district. In each site, these uncontrolled mining residues present a high level of metallic sulphide and generate, during rainy periods, leaching products which have physical and chemical characteristics of acid mine drainage (AMD). These percolates display an acidic pH ranging from 2.5 to 5.2, a high electric conductivity, large amounts of sulphate and heavy metals, especially under dissolved form (e.g. Cd: 17.34 mg l(-1); Fe: 1734 mg l(-1); Zn: 3935 mg l(-1)). Except for Pb, the free ionic form is the most abundant metallic form, as showed by calculations using the speciation GEOCHEM program. The analysis of water and sediments of the surrounding superficial aquatic ecosystems shows a modification of water chemical facies and an enrichment in heavy metals, mainly under the solid phase for Fe, Pb, Cu, Co, Cr and Ni, and under dissolved fraction for Cd and Zn. The dissolved fraction of these metals is dominated by the free ionic form, considered as available for organisms. Furthermore, sediments contain important quantities of heavy metals (Pb: 1450 microg g(-1), Zn: 1562 microg g(-1)) with an available fraction which is higher than 40% for the Cd and Zn. The abundance of trace elements (free ionic and available forms) in water and sediment presents a durable risk of their transfer to food chains.

Molluscicidal Activity of the Different Morphological Organs of Gnidia Kraussiana Meisn &Quot;Abu Gotna&Quot; Family Thymelaeaceae. *J trop med hyg. 1979 nov-dec; 82(11-12):242-7. [The journal of tropical medicine and hygiene]: J Trop Med Hyg*. Chem Codes: Chemical of Concern: PSM Rejection Code: BIOLOGICAL TOXICANT.

ABSTRACT: The molluscicidal activity of Gnidia kraussiana Meisn leaf, stem and root was studied. Each morphological part was extracted with cold and boiling water, different organic solvent and successively with organic solvents of increasing polarity. Throughout it was found that the extracts of the root were the most potent followed by the stem. Boiling water extracts were more potent than cold water extracts, while in case of extraction with different organic solvents, the petroleum ether extracts of the root and stem were the most potent, while for the leaf, the ethanolic extract was the most potent. On successive extraction, the petroleum ether extracts of all organs were the most potent. Saponification of the petroleum ether extract of the root was carried out and the activity of the different fractions were tested. Different extract fractions were obtained from the 80 per cent ethanolic percolate of the root. Some of the physical properties and the phytochemical screening of the successive extractives of the three organs were studied.

Part C: Environ Carcinogenesis and Ecotoxicology Rev 1996, C14, 1 A quant. structure-activity relationship (QSAR) investigation was done for the acute oral mammalian toxicity (LD50) of a set of 54 organophosphorus pesticide compds. The compds. were represented with calcd. mol. structure descriptors, which encoded their topol., electronic, and geometrical features. Feature selection was done with a genetic algorithm to find subsets of descriptors that would support a high quality computational neural network (CNN) model to link the structural descriptors to the - log(mmol/kg) values for the compds. The best seven-descriptor non-linear CNN model found had an rms error of 0.22 log units for the training set compds. and 0.25 log units for the prediction set compds. [on SciFinder (R)] 1062-936X

(SFE) with carbon dioxide. In fruit and vegetable samples, which typically contain 80-95% water, moisture acts to increase SFE recoveries of many polar pesticides, but a drying agent should be used to control water in SFE. Hydromatrix, a prevalent drying agent, has many desirable characteristics, but it reduces recovery of certain important pesticides, such as methamidophos, acephate, and omethoate. $MgSO_4$ has been shown previously to be applicable for the extn. of methamidophos and 6 other pesticides, but $MgSO_4$ has practical disadvantages in its use. Properties and SFE results with the individual drying agents and their combination were evaluated. Simultaneous recoveries for polar and nonpolar pesticides were achieved for 71 pesticides fortified in apple using a mixt. of 2 + 1 + 2 $MgSO_4.H_2O$-Hydromatrix-sample for extn. The advantages of each drying agent were maintained by their combination. The anal. of real

samples, however, showed that more study was needed to improve recoveries of nonpolar pesticides. [on SciFinder (R)] 0003-2654 pesticide/ supercrit/ fluid/ extn/ drying/ agent

High and intermediate levels of resistance were found to cypermethrin and thiodicarb, resp., in H. virescens. No increased tolerance was seen to profenofos in H. virescens and no increased tolerance to any insecticide tested was detected in H. zea. Significant resistance to Bacillus thuringiensis Berliner was not obsd. in either species during the season. No synergism was detected in a bioassay using insecticide mixts. and piperonyl butoxide on a resistant strain of H. virescens. Multiple resistance in H. virescens is still evident and resistance to pyrethroids appears to be stabilized. [on SciFinder (R)] 1059-2644 insecticide/ resistance/ Helicoverpa/ Heliothis

Chem Codes: Chemical of Concern: PSM Rejection Code: IN VITRO.

1. 1.The molecular weights of a series of synthetic myosin filaments have been measured, using the transport-concentration dependence theory of Rowe, A.J. [Biopolymers, 1977, 16, 2595-2611]. It is shown that for preparations of narrow length distribution (0.60-0.77 [mu]m), N, the number of myosin molecules/14.3 nm varies between 3 and 6. 2. 2.The reduced specific viscosity of synthetic myosin filaments has been measured as a function of both concentration and shear rate. From the concentration dependence at zero rate of shear, a value for the `swelling' of the filaments Vrms/ovbar[nu] = 2.3 has been calculated. 3. 3.The frictional coefficient of synthetic myosin filaments has been shown to be anomalously but reproducibly high, as compared to that of prolate ellipsoids of the same length and mass. This additional frictional drag has been numerically characterised by a `frictional increment', fi = 1.76 +/- 0.11. 4. 4.A procedure has been devised whereby for any elongated structure which can be assumed to show the same (or other known) fi value, the molecular weight can be estimated from so (extrapolated sedimentation coefficient) and 2b (length) alone. 5. 5.An s0 value for natural A-filaments, isolated from rabbit psoas muscle, has been determined by the active enzyme centrifugation technique. From this value, s0 = 132 +/- 3 S, a molecular weight of 1.20 [middle dot] 108 has been computed by the new procedure, for preparations of average length 1.27 [mu]m. 6. 6.Contingent upon the validity of the assumptions

used (see 4 above) the N value is computed as 3.1 +/- 0.2, consistent with the native, fully intact A-filament having three-fold symmetry, containing 294 myosin molecules, and having a molecular weight based upon myosin and C-protein of 1.31 [middle dot] 108.

365. Engel, Andreas, van Driel, Roel, and Driedonks, Rene (1982). A proposed structure of the prolate phage T4 prehead core: An electron microscopic study. *Journal of Ultrastructure Research* 80: 12-22.
Chem Codes: Chemical of Concern: PSM Rejection Code: CHEM METHODS, BACTERIA.

The major core protein of T4 preheads, gp22, self-assembles into filaments that are about 9.5 nm wide, 2 to 3 nm thick, and have an undefined length. The mass of such ribbons, determined by electron scattering in the STEM, is 19 300 daltons/nm, indicating one gp22 molecule (Mr = 27 000) per 1.4 nm. The surface of in vitro assembled, freeze-dried T4 prehead cores shows 9-nm-spaced modulations, running at an angle of 35[degree sign] to the equator of the structure. This result, combined with the fact that the core of abnormally elongated preheads can be described as a six-start helix (), suggests that the surface of the core is formed by six gp22 filaments arranged in a distorted helical way. At one or both ends, the filaments are apparently attached to a special structure, possibly containing gp20. On this basis a simple mechanism for the determination of size and prolate shape of the T4 head is discussed.

Citations: US Environmental Protection Agency; Washington State Epidemiologic Study Project 1976 Self-reported work histories are often the only means of estg. occupational exposures in epidemiol. research. The objective of this study was to examine the accuracy of recall of historical pesticide use among orchardists. All 185 orchardists in this study had participated previously in a cohort study of men occupationally exposed to pesticides. In that study (1972 to 1976), subjects were interviewed annually and asked to list pesticides used since the last interview. In 1997, 265 of the 440 presumed-living orchardists from the original cohort were successfully recontacted and asked to complete a detailed questionnaire concerning their lifetime use of pesticides; 185 (69.8% of farmers successfully contacted) agreed. Considering the 1972-1976 data as the std., sensitivity and specificity of recall were calcd. for certain pesticides and pesticide categories. Sensitivity of recall was good to excellent (0.6-0.9) for the broad categories of insecticides, herbicides, and fungicides, for heavily used chem. classes, such as organophosphates and organochlorines, and for commonly used pesticides; it was lower and more variable (0.1-0.6) for specific pesticides. Recall specificity was greatest (0.7-0.9) for the least used pesticides and chem. classes, such as dithiocarbamates and manganese-contg. pesticides, and was generally modest for the rest (0.5-0.6). There was no evidence of selection bias between study participants and nonparticipants. In conclusion, recall accuracy was good for commonly used pesticides and pesticide categories. This level of recall accuracy is probably adequate for epidemiol. analyses of broad categories of pesticides, but is a limitation for detecting more specific assocns. [on SciFinder (R)] 1053-4245

1861-32-1; 1912-24-9; 1918-02-1; 1918-16-7; 2303-17-5; 2539-17-5; 4684-94-0; 23564-05-8; 33245-39-5; 35367-38-5; 41198-08-7; 51218-45-2 Role: ADV (Adverse effect, including toxicity), BIOL (Biological study) (toxicity of, prediction of, QSARs in relation to) A structure-activity model (QSAR) of rat oral LD50 toxicity based on D. magna median lethal concn. (LC50) values and structural parameters was developed. Even though the 2 species represent widely different animals, it is possible to achieve reasonably good predictions of the mammalian endpoint. A regression equation based on 147 diverse chems. for which both endpoints were available has a correlation coeff. square of 0.75. The independent parameters consisted of mol. connectivity indexes, both simple and valence adjusted, and substructural keys acting as covariates for the different series of compds. in the data base. Fifty percent of the compds. can be predicted within a factor of 1.7 and 95% within a factor of 6 of the actual values. Thus it is possible to develop interspecies QSAR equations for toxicol. and, possibly, efficacy endpoints. The same principles can be used to model different routes of administration. An acetone-acetonitrile mixt. is used to initially ext. OPPs from milk and infant formula samples, followed by partition of the analytes into dichloromethane (DCM). Dichloromethane is removed on a rotary evaporator and the residue taken up in acetonitrile (ACN) for cleanup on a C-18 (octadecylsiloxane bonded silica) (SPE) cartridge. ACN eluate is evapd. under nitrogen and the residue taken up in acetone for GC-FPD detn. Initial studies showed mean recoveries for 28 of 29 OPPs in whole milk fortified at 0.10 ppm ranged between 69 and 99% with a relative std. deviation (RSD) of 1.0-9.7%. Whole/chocolate/skim-milk and four infant formula products fortified at 0.02 ppm gave mean recoveries of 64-103% with RSDs between 1.9 and 20.9% for 24 of 29 OPPs. Excluding skim milk, recoveries for Dichlorvos, Methamidophos, Mevinphos E, and Acephate ranged between 47 and 89%. Sample exts. were extremely clean and posed no difficulty to the GC system. The procedure is faster and less costly than Assocn. of Official Anal. Chemists (AOAC) procedures and allows for detn. of a broad spectrum of OPPs. 371. Eylar, E. H. and Thompson, Millie (1969). Allergic encephalomyelitis: the physico-chemical properties of the basic protein encephalitogen from bovine spinal cord. *Archives of Biochemistry and Biophysics* 129: 468-479.
Chem Codes: Chemical of Concern: PSM Rejection Code: IN VITRO.

A protein encephalitogen, isolated in a homogeneous state from bovine spinal cord, was found to have unusual properties. It was highly basic, containing 38 moles/ mole of basic amino acids (arginine, lysine, histidine) and only 7 moles/mole of acidic amino acids (glutamic and aspartic acid); the calculated isoionic point exceeded 12. Only one tryptophan (determined by three independent methods) and two methionine residues were present; no carbohydrate or lipid was associated with the isolated protein. Although similar to certain histone fractions, it differed from these proteins in its much higher content of histidine, glycine, and serine, and its lower content of alanine. The N-terminal position is blocked. The molecular weight determined by sedimentation equilibrium techniques was 16,400 daltons; by sedimentation-viscosity, 16,200; and by UV absorption studies based on the tyrosine-tryptophan content, 16,200. Estimates of molecular weight based on the amino acid analysis gave values of 15,500-18,200 daltons. An intrinsic viscosity of 9.27 ml/g and viscosity increment of 12.9 were found. From these data an axial ratio (a/b) of approximately 10:1 (assuming no hydration and a prolate ellipsoid) was calculated, revealing that the molecule is highly unfolded and approximates a rod-like shape. This property accounts for the unexpected behavior of this basic protein on gel nitration which has led to erroneously high molecular weight values. A small degree of aggregation was observed as indicated by the high molecular weight estimate of 22,300 found near the cell bottom using a long-column sedimentation equilibrium technique. No evidence of aggregation was observed at pH 2.6, 7.0, or 9.5 during sedimentation velocity studies. An S020,w value of 1.72S was found at pH 2.6, ionic strength 0.25. Considerable variation of the S20,w was found with protein concentration, but not with pH. The highly extended conformation of the Al molecule, found from viscosity studies, is compatible with its resistance to denaturation; no loss in encephalitogenic activity was found following heating at 100 [degree sign] for 1 hr, treatment with 8 urea for 8 hr, or incubation at pH 10.0 for 8 hr. Moreover, these procedures do not diminish interaction with antibody measured by the Ouchterlony and passive hemagglutination inhibition tests. Polyacrylamide gel electrophoresis also revealed no drastic changes in conformation arising from these procedures. It was concluded from these data that hydrophobic and hydrogen bonding play a minor role in the overall conformation of the A1 protein molecule. This property is of interest in considering the role of this protein as a membrane component. http://www.sciencedirect.com/science/article/B6WB5-4DXBG66-B5/2/a0c07226224256b7b36e4050fc112dd2

Chem Codes: Chemical of Concern: PSM Rejection Code: BACTERIA.

Conjugal transfer of lactose-fermenting ability (Lac+) and lytic phage resistance (Lpr+) was demonstrated in four matings between Lactococcus lactis ssp. lactis C2, phage resistant mutant donor strains C21, C23 and C26 and the C2 derivative LM2302 plasmid free recipient strain. Transconjugants were selected with Lac+ Emr and/or Str phenotypes. Lac+ was transferred from donor strains to Lac- Emr and r Str phage sensitive recipient strains at a frequency of 10-6 to 10-8 revealing that Lac+ and subsequently Lpr+ were transferred. Although clumping (Clu) effects with a subsequent high frequency transconjugation (Hft) have been observed before in related strains, it was not evident in this case. Phage assays with Argentine (ARG) and United States (US) phage revealed that recipient strains were Lpr-. Because the transconjugants had the same lytic pattern as the corresponding donor strain, it is apparent that the unselected Lpr+ trait was cotransferred with the Lac+ marker on a 45 kb plasmid. A significant reduction in bacteriophage adsorption and failures in plaque formations for the ARG and the US prolate phages in all Lpr+ strains was also observed. These results suggest that the Lpr+ trait is mobilized by conjugal transfer. http://www.sciencedirect.com/science/article/B6WFP-4F1JC6H-9/2/e1b99d97ba101bd95bdfe396125ee796

374. Farin, Dina and Avnir, David (1989). The effects of the fractal geometry of surfaces on the adsorption conformation of polymers at monolayer coverage part I. The case of polystyrene. *Colloids and Surfaces* 37: 155-170.
Chem Codes: Chemical of Concern: PSM Rejection Code: CHEM METHODS.

Surface geometry effects on the adsorption conformations of polymers under plateau conditions are found and analyzed by using fractal geometry considerations. The re-analysis of many adsorption studies, with special emphasize on polystyrene, shows that while on a flat surface a dense packing is formed, distorting the solution conformation into a prolate shape, on highly porous objects the solution conformation changes only slightly upon adsorption. These general trends show a surprisingly low sensitivity to the chemical nature of the polymer--solvent--surface system, emphasizing the crucial role of environmental geometry in determining adsorption conformations. http://www.sciencedirect.com/science/article/B6W92-4400WNM-93/2/305e9963b7da5b4e7b56c82670a91fe1

ABSTRACT: PESTAB. A study was made of 60 sets of real data for 15 different pesticides;

formetanate, carbaryl, propoxur, mexacarbate, dioxacarb, dichlorvos, naled, trichlorfon, fospirate, GC-6506, phosmet, fenitrothion, azinphosmethyl, parathion, and methyl parathion, for the purpose of developing appropriate experimental designs for studying the toxic properties of these agents. The quantal responses for the dose groups in this data ranged from 1% to 90%. The data could be represented equally well by a probit or logit transformation. Investment in 7 times as many animals would greatly increase the confidence in estimating the parameters of the model and in predicting the dose at the low end of the dose response scale. It was also shown that the estimation of a safe dose for a specified risk was greatly influenced by the choice of experimental design and method of extrapolation.

ABSTRACT: The impact of extensively used arsenic-containing herbicides on groundwater beneath golf courses has become a topic of interest. Although currently used organoarsenicals are less toxic, their application into the environment may produce the more toxic inorganic arsenicals. The objective of this work was to understand the behavior of arsenic species in percolate water from monosodium methanearsonate (MSMA) applied golf course greens, as well as to determine the influences of root-zone media for United State Golf Association (USGA) putting green construction on arsenic retention and species conversion. The field test was established at the Fort Lauderdale Research and Education Center (FLREC), University of Florida. Percolate water was collected after MSMA application for speciation and total arsenic analyses. The results showed that the substrate composition significantly influenced arsenic mobility and arsenic species transformation in the percolate water. In comparison to uncoated sands (S) and uncoated sands and peat (S + P), naturally coated sands and peat (NS + P) showed a higher capacity of preventing arsenic from leaching into percolate water, implying that the coatings of sands with clay reduce arsenic leaching. Arsenic species transformation occurred in soil, resulting in co-occurrence of four arsenic species, arsenite (As(III)), arsenate (As(V)), monomethylarsonic acid (MMA), and dimethylarsinic acid (DMA) in percolate water. The results indicated that substrate composition can significantly affect both arsenic retention in soil and arsenic speciation in percolate water. The clay coatings on the soil particles and the addition of peat in the soil changed the arsenic bioavailability, which in turn controlled the microorganism-mediated arsenic transformation. To better explain and understand arsenic transformation and transport after applying MSMA in golf green, a conceptual model was proposed.

378. Fenn, M. E. , Poth, M. A., and Arbaugh, M. J. (A Throughfall Collection Method Using Mixed Bed Ion Exchange Resin Columns. *Scientificworldjournal. 2002, jan 15; 2:122-30. [Thescientificworldjournal]: ScientificWorldJournal.*
Chem Codes: Chemical of Concern: PSM Rejection Code: CHEM METHODS.

ABSTRACT: Measurement of ionic deposition in throughfall is a widely used method for measuring deposition inputs to the forest floor. Many studies have been published, providing a large database of throughfall deposition inputs to forests. However, throughfall collection and analysis is labor intensive and expensive because of the large number of replicate collectors needed and because sample collection and chemical analyses are required on a stochastic precipitation event-based schedule. Therefore we developed and tested a throughfall collector system using a mixed bed ion exchange resin column. We anticipate that this method will typically require only one to three samplings per year. With this method, bulk deposition and bulk throughfall are collected by a funnel or snow tube and ions are retained as the solution percolates through the resin column. Ions retained by the resin are then extracted in the same column with 2 N KCl and analyzed for nitrate and ammonium. Deposition values in throughfall from conventional throughfall solution collectors and colocated ion exchange samplers were not significantly different during consecutive 3- and 4-month exposure periods at a high (Camp Paivika; >35 kg N ha(-1) year(-1)) and a low deposition (Barton Flats; 5-9 kg N ha(-1) year(-1)) site in the San Bernardino Mountains in southern California. N deposition in throughfall under mature pine trees at Camp Paivika after 7 months of exposure was extremely high (87 and 92 kg ha-1 based on the two collector types) compared to Barton Flats (11 and 13 kg ha(-1)). A large proportion of the N deposited in throughfall at Camp Paivika occurred as fog drip, demonstrating the importance of fog deposition as an input source of N at this site. By comparison, bulk deposition rates in open areas were 5.1 and 5.4 kg ha(-1) at Camp Paivika based on the two collector types, and 1.9 and 3.0 kg ha(-1) at Barton Flats.

Duplicate diets were collected from seven children living in the Seattle metropolitan area and six children living in Chelan and Douglas counties in Central Washington. Diet samples were collected from each child in the summer and again in the fall, and total daily diets were divided into four food categories: fresh fruits and vegetables, beverages, processed foods, and dairy products. A total of 88 individual food category samples were collected and analyzed for 15 organophosphorous (OP) pesticides. Three of the 13 children had no detectable OP pesticides in either of their diet samples, and 14 of the 26 duplicate diets did not contain detectable levels of OP pesticides. Sixteen individual food category samples contained detectable levels of at least one OP pesticide and two of these samples contained detectable levels of two OP pesticides. Of the 15

targeted pesticides, 6 were detected: azinphosmethyl, chlorpyrifos, malathion, methidathion, methyl parathion, and phosmet. Azinphosmethyl was detected most frequently (10% of all samples), particularly in samples contg. apples or apple juice. The fresh fruits and vegetable category had the most frequent pesticide detns., followed by beverages. OP pesticides were not present at detectable levels in any of the dairy samples. Malathion was the only OP pesticide detected in processed food samples, appearing in 4 of the 26 samples (15%). No detections were above the legal tolerances for residues on produce, however the acute population -adjusted ref. dose (aPAD) for chlorpyrifos exposure of 1.7 mg/kg/day was exceeded by one subject during one sampling event. This subject's cumulative daily dose of chlorpyrifos equiv. was estd. to be 2.5 mg/kg/day. [on SciFinder (R)] 1053-4245 organophosphorous/ pesticide/ exposure/ child/ food/ contamination

Current pesticide health risk assessments in the United States require the characterization of aggregate exposure and cumulative risk in the setting of food tolerances. Biol. monitoring can aggregate exposures from all sources and routes, and can integrate exposures for chems. with a common mechanism of action. Its value was demonstrated in a recent study of organophosphorus (OP) pesticide exposure among 109 children in an agricultural community in Washington State; 91 of the children had parents working in agriculture. We estd. individual OP pesticide doses from urinary metabolite concns. with a deterministic steady state model, and compared them to toxicol. ref. values. We evaluated doses by assuming that metabolites were attributable entirely to either azinphos-Me or phosmet, the two OP pesticides used most frequently in the region. Creatinine-adjusted av. dose ests. during the 6- to 8-wk spraying season ranged from 0 to 36 mg/kg/day. For children whose parents worked in agriculture as either orchard applicators or as fieldworkers, 56% of the doses estd. for the spray season exceeded the U.S. Environmental Protection Agency (EPA) chronic dietary ref. dose, and 19% exceeded the World Health Organization acceptable daily intake values for azinphos-Me. The corresponding values for children whose parents did not work in agriculture were 44 and 22%, resp. The percentage of children exceeding the relevant ref. values for phosmet was substantially lower (< 10%). Single-day dose ests. ranged from 0 to 72 mg/kg/day, and 26% of these exceeded the EPA acute ref. dose for azinphos-Me. We also generated dose ests. by adjustment for total daily urine vol., and these ests. were consistently higher than the creatinine-adjusted ests. None of the dose ests. exceeded the empirically derived no-observable-adverse-effect levels for these compds. The study took place in an agricultural region during a period of active spraying, so the dose ests. for this population should not be considered representative of exposures in the general population. The findings indicate that children living in agricultural regions represent an important subpopulation for public health evaluation, and that their exposures fall within a range of regulatory concern. They also demonstrate that biol. based exposure measures can provide data for health risk evaluations in such populations. Citations: 10) Lu, C; Environ Health Perspect 2001, 109, 299 We measured 2 di-Et organophosphorus (OP) pesticides - chlorpyrifos and parathion - in residences, and their metabolic byproducts, in the urine of children 6 yr old or younger in a central Washington State agricultural community. Exposures to 2 di-Me OP pesticides (azinphos-Me and phosmet) in this same population were reported previously. We categorized children by parental occupation and by household proximity to pesticide-treated farmland. Median chlorpyrifos house dust concns. were highest for the 49 applicator homes (0.4 mg/g), followed by the 12 farm-worker homes (0.3 mg/g) and the 14 nonagricultural ref. homes (0.1 mg/g), and were statistically different ($p <0.001$); we obsd. a similar pattern for parathion in house dust. Chlorpyrifos was measurable in the house dust of all homes, whereas we found parathion in only 41% of the homes. 24% Of the urine samples from study children had measurable 3,5,6-trichloro-2-pyridinol (TCPy) concns. [limits of quantitation (LOQ) = 8 mg/L], and 7% had measurable 4-nitrophenol concns. (LOQ = 9 mg/L). Child urinary metabolite concns. did not differ across parental occupational classifications. Homes in close proximity (200 ft/60 m) to pesticide-treated farmland had higher chlorpyrifos ($p = 0.01$) and parathion ($p = 0.014$) house dust concns. than did homes farther away, but this effect was not reflected in the urinary metabolite data. Use of OP pesticides in the garden was assocd. with an increase in TCPy concns. in children's urine. Parathion concns. in house dust decreased 10-fold from 1992 to 1995, consistent with the discontinued use of this product in the region in the early 1990s. Citations: US Environmental Protection Agency; Implementing the Food Quality Protection Act: Progress Report 1999 Children can be exposed to pesticides from multiple sources and through multiple pathways. In addn. to the std. pathways of diet, drinking water and residential pesticide use, children in agricultural communities can be exposed to pesticides used in agricultural prodn. A research program on children and pesticides was established at the University of Washington (UW) in 1991 and has focused on two major exposure pathway issues: residential proximity to pesticide-treated farmland and transfer of pesticides from the workplace to the home (paraoccupational or take-home exposure). The UW program selected preschool children of agricultural producers and farm workers in the tree fruit region of Washington state as a population that was likely to have elevated exposures from these pathways. The organophosphorus (OP) pesticides were selected as a common class of chems. for anal. so that

issues of aggregate exposure and cumulative risk could be addressed. This paper provides an overview of key findings of the research group over the past 8 yr and describes current studies in this field. Soil and housedust concns. of OP pesticides were elevated in homes of agricultural families (household members engaged in agricultural prodn.) when compared to non-agricultural ref. homes in the same community. Dialkyl phosphate metabolites of OP pesticides measured in children's urine were also elevated for agricultural children when compared to ref. children and when compared to children in the Seattle metropolitan area. Proximity to farmland was assocd. with increased OP pesticide concns. in housedust and OP pesticide metabolites in urine. Current studies include a community-based intervention to reduce parental transfer of pesticides from the workplace, and a systematic investigation of the role of agricultural spray drift in children's exposure to pesticides. 1. 1. [alpha]-Crystallins were isolated from bovine, canine and ovine ocular lenses by chemical methods. 2. 2. An alkaline-modified bovine [alpha]-crystallin was prepared by subjecting normal bovine [alpha]-crystallin to pH > 9[middle dot]5 with subsequent precipitation at pH 5[middle dot]1. 3. 3. Electrophoretic mobilities of the various [alpha]-crystallins were determined by moving boudary electrophoresis in Na-veronal and Tris-veronal buffers. Canine [alpha]-crystallin had the highest mobility. 4. 4. The [alpha]-crystallins were characterized by sedimentation, viscosity and partial specific volume determinations. 5. 5. Molecular weights were determined by means of sedimentation equilibrium. The values were: bovine, 1,035,000; alkaline-modified bovine, 499,000; ovine, 1,047,000; and canine, 924,000. 6. 6. Molecular weights and dimensions were calculated assuming prolate and oblate ellipsoidal and spherical models from sedimentation, viscosity and partial specific volume data. http://www.sciencedirect.com/science/article/B6T2R-47GB661-R8/2/73a09dbebbfe777f9dc6bf2786d41e83

(SPME) followed by gas chromatog. with nitrogen-phosphorus detection was developed for the purpose of detg. 18 organophosphorus pesticide residues in honeybee samples (Apis mellifera). The extn. capacities of polyacrylate and poly(dimethylsiloxane) fibers were compared. The main factors affecting the SPME process, such as the absorption time profile, salt, and temp., were optimized. The method involved honeybee sample homogenization, elution with an acetone:water soln. (1:1) and diln. in water prior to fiber extn. Moreover, the matrix effect on the extn. was evaluated. In samples spiked at the 0.2 mg kg-1 level, the coeff. variation was between 1 and 13% and the detection limits were below 10 mg kg-1. The SPME procedure was found to be quicker and more cost-effective than the solvent extn. method commonly used. The method was applied successfully to environmental screening. Parathion Me was detected and confirmed in the real samples analyzed. Liq. chromatog.-atm. pressure chem. ionization-mass spectrometry (LC-APCI-MS) expts. with pos. (PI) and neg. (NI) ion modes were optimized for the anal. of 22 organophosphorus pesticides in honeybee samples. The extn. required 3 g of sample, which was extd. with acetone. The ext. was purified with coagulating soln. and reextd. with Cl2CH2. Pesticides studied could be detected by both ionization modes except for parathion, parathion-Me, and bromophos, which did not give signals in PI mode, and triazophos, which was not detected in NI mode. Fragmentation voltage and vaporizer temp. were optimized to achieve the highest sensitivity. The spectra profile of each pesticide in PI mode showed the [M + H]+ ion as the main signal, whereas in NI mode only fragment ions were shown. The detection limit obtained in selected ion monitoring mode ranged from 1 to 15 mg kg-1. The av. recoveries from spiked honeybees at various concn. levels (0.5-5 mg kg-1) exceeded 65% with relative std. deviations of 4-15%. The method was applied to real samples, in which residues of coumaphos and dimethoate were detected. [on SciFinder (R)] 0021-8561 organophosphorus/ pesticide/ LC/ atm/ pressure/ chem/ ionization/ MS

Citations: 20) Ferrer, I; J Chromatogr A 2005, 1082, 81 An automated mol.-feature database (MFD) consisting of the exact monoisotopic mass of 100 compds., at least one exact mass product ion for each compd., and chromatog. retention time were used to identify pesticides in food and water samples. The MFD software compiles a list of accurate mass ions, excludes noise, and compares them with the monoisotopic exact masses in the database. The screening criteria consisted of +-5 ppm accurate mass window, +-0.2 min retention time window, and a min. 1000 counts (signal-to-noise (S/N) ratio of .apprx.10:1). The limit of detection for 100 tested compds. varied from <0.01 mg/kg for 72% of the compds. to <0.1 mg/kg for 95% of the compds. The

MFD search was useful for rapid screening and identification of pesticides in food and water, as shown in actual samples. The combined use of accurate mass and chromatog. retention time eliminated false positives in the automated anal. The major weakness of the MFD is matrix interferences and loss of mass accuracy. Strengths of the MFD include rapid screening of 100 compds. at sensitive levels compared with a manual approach and the ease of use of the library for any accurate mass spectrometer instrumentation capable of routine sub-5-ppm mass accuracy. Citations: 34) Boswell, S; Int J Mass Spectrom Ion Processes 1990, 99, 139 Upon the supersonic expansion of helium mixed with vapor from an org. solvent (e.g. methanol), various clusters of the solvent with the sample mols. can be formed. As a result of 70 eV electron ionization of these clusters, cluster chem. ionization (cluster CI) mass spectra were obtained. These spectra were characterized by the combination of EI mass spectra of vibrationally cold mols. in the supersonic mol. beam (cold EI) with CI-like appearance of abundant protonated mols., together with satellite peaks corresponding to protonated or nonprotonated clusters of sample compds. with 1-3 solvent mols. Like CI, cluster CI preferably occurs for polar compds. with high proton affinity. However, in contrast to conventional CI, for nonpolar compds. or those with reduced proton affinity the cluster CI mass spectrum converges to that of cold EI. The appearance of a protonated mol. and its solvent cluster peaks, plus the lack of protonation and cluster satellites for prominent EI fragments, enable the unambiguous identification of the mol. ion. In turn, the insertion of the proper mol. ion into the NIST library search of the cold EI mass spectra eliminates those candidates with incorrect mol. mass and thus significantly increases the confidence level in sample identification. Also, mol. mass identification is of prime importance for the anal. of unknown compds. that are absent in the library. Examples are given with emphasis on the cluster CI anal. of carbamate pesticides, high explosives and unknown samples, to demonstrate the usefulness of Supersonic GC/MS (GC/MS with supersonic mol. beam) in the anal. of these thermally labile compds. Cluster CI is a practical ionization method, due to its ease-of-use and fast instrumental conversion between EI and cluster CI, which involves the opening of only one valve located at the make-up gas path. The ease-of-use of cluster CI is analogous to that of liq. CI in ion traps with internal ionization, and is in marked contrast to that of CI with most other std. GC/MS systems that require a change of the ion source. Abstract: Sect. Capparis is represented by a single species, Capparis spinosa L., divided into several intraspecific taxa showing plesiomorphic features and disjunct distributions in the Old World. Leaf surface and pollen features were investigated in the whole group by SEM and light microscope observations. The section is characterized by simple hairs, a reticulate to undulate cuticle, anomocytic stomata surrounded by a peristomal rim, and trizonocolporate, prolate pollen grains. The characteristics of the indumentum appear constant, while the studied taxa are fairly differentiated with respect to cuticular patterns and dimensions of the stomata, and show slight differences in pollen size and exine surface. This micromorphological evidence, coupled with other phenotypic features, supports the placement of this section at the base of the genus Capparis in the paleotropical area. Considering the striking geographic disjunction and symplesiomorphies of the group, its biogeographical and systematic aspects are also discussed.

Abstract: During the Lindenberg Aerosol Characterization Experiment (LACE 98), airborne measurements of aerosol size distribution, fine-particle concentration, particle absorption coefficient, backscatter coefficient, depolarization, and chemical composition as well as ground-based measurements of spectral particle optical depth and of spectral backscatter and extinction coefficients were performed in the aerosol column above Lindenberg, Germany. We compare the measured optical parameters with calculations from the size distributions, which assume the aerosol to consist of sulfuric acid near the tropopause and mixtures of ammonium sulfate and soot in the remaining column. We obtain closure to within 25% for the optical depth of a column, which includes a biomass-burning aerosol of North American origin, and infer a soot volume fraction of 35% for this aerosol. Assuming spheroidal particles of prolate shape and the average aspect ratio of the particles to be 1.3 in the biomass-burning aerosol layer, the calculated depolarization agrees with the lidar measurement, whereas comparing the spectral backscatter coefficient shows the soot to be externally mixed with the nonabsorbing particles. With the two-stream approximation, we estimate the local, instantaneous, cloud-free radiative forcing of the biomass-burning aerosol at the tropopause to -5.8 W/m super(2) with a corresponding optical depth of 0.09 at 710 nm wavelength and solar zenith angle of 56 degree . The radiative forcing for the biomass-burning aerosol is as sensitive to a change in state of mixture, either external or internal, as to a change in surface albedo, ocean to coniferous forest.

391. Field, Richard, Masters, Hugh, and Singer, Melvin (1982). Status of porous pavement research. *Water Research* 16: 849-858.
Chem Codes: Chemical of Concern: PSM Rejection Code: METHODS.

This paper discusses the U.S. Environmental Protection Agency's porous pavement research program along with the economics, advantages, potential applications, and status and future research needs of porous pavements. Porous pavements are an available stormwater management technique which can be used on parking lots and low volume roadways to reduce both stormwater runoff volume and pollution. In addition, groundwater recharge is enhanced. Also, cost reductions result due to elimination of curbs, drains, and small sized storm sewers. Porous asphalt pavements consist of a relatively thin course of open graded asphalt mix over a deep base of large size crushed stones. Water can be stored in the crushed stone base until it can percolate into the subbase or drain laterally. Other porous pavement types include concrete lattice blocks and a porous concrete mix. http://www.sciencedirect.com/science/article/B6V73-48BDNP1-RK/2/34bc9c6796097a14030fc962dfc7b359

ABSTRACT: The aim of the second phase of the Pollution Atmosphérique et Affections Respiratoires Chroniques (PAARC) study, started in 1974, was to compare the long-term mortality between populations living in areas with different air pollution levels. In Bordeaux (France), four different areas were concerned by the study. The black smoke measures were realized between 1974 and 1981. After 1981, the stations set specifically for the study were not used any more. The purpose of this study was to estimate the evolution of air pollution in those areas between 1982 and 1997 using the measures of 12 Association de Prévention de la Pollution Atmosphérique (APPA) stations located in Bordeaux city but not in the PAARC areas. The method used was divided in three phases: a correlation study between the stations of the different networks, a selection of the pertinent stations and the setting up of indicators using the arithmetic means method. Monthly means concentrations were estimated from January 1982 to December 1997. Models showed a decrease in black smoke levels whatever the area. The difference in level from one area to another, existing between the areas in 1974, was still with predicted values in 1997, but less important. Black smoke mean concentration for 1982-1997 was, respectively, 16.4 and 16.2 microg/m3, in areas 1 and 2. It was a little bit higher in area 3 with 18.9 microg/m3. Area 4 still has the highest level with 26.3 microg/m3. To conclude, this method enabled to assess different air pollution levels at different times in the four areas of the PAARC study in Bordeaux. Those levels could be used to study the impact of the air pollution on long-term mortality on populations living in the areas considered.

Extn. of the sample with acetonitrile is followed by a salting-out step. Co-extractives are removed by passing a portion of the acetonitrile ext. through an octadecyl (C18) solid-phase extn. cleanup cartridge and then, in a 2nd cleanup, through a carbon cartridge coupled to an amino Pr cartridge. Detn. is by gas chromatog. with mass-selective detection in the selected-ion monitoring mode, and by liq. chromatog. with post-column reaction and fluorescence detection for N-Me carbamates. The method has been used for anal. of various fruits and vegetables, such as apple, banana, cabbage, carrot, cucumber, lettuce, orange, pear, pepper, and pineapple. Limits of detection range between 0.02 and 1.0 mg/kg for most compds. Over 80% of the compds. have a limit of detection of ?0.04 mg/kg. Abstract: A new, controlled, environment facility for growing trees was built at Joensuu, Finland, between 1996 and 1998. It consists of four large rooms called dasotrons, with four large root pots in each. Each room is a separate unit, with independent control of air and soil temperature, air humidity and light. The environmental variables can be controlled to simulate conditions ranging from tropical to boreal. The controller set-points can be programmed locally or through a central

control system running on a PC. The floor area and height of the rooms allows us to grow small trees (up to 3.7 m height) for several growing seasons. In each dasotron, there are four cylindrical pots with a removable upper section. There are access holes in the walls of the pots for the installation of sensors and minirhizotron tubes. Each pot has a drain, with valves, at the bottom to enable the removal of excess water or the collection of percolate samples. The operation of the facility was tested during one simulated annual growing cycle. During this test period, the dasotrons worked reliably and no systematic differences were found in the environmental conditions or in the growth of Norway spruce seedlings between the dasotrons. This new facility will enable diverse physiological and ecophysiological studies to be carried out on the responses of trees to their below- and above-ground environment.

399. Flicker, P. F., Milligan, R. A., and Applegate, D. (1991). Cryo-electron microscopy of S1-decorated actin filaments. *Advances in Biophysics* 27: 185-196.
Chem Codes: Chemical of Concern: PSM Rejection Code: IN VITRO, CHEM METHODS.

We have applied techniques for cryo-electron microscopy, combined with image processing, to both S1-decorated native thin filaments and S1-decorated actin filaments. In our reconstruction the actin subunit has a prolate ellipsoid shape and is composed of two domains. The long axis of the monomer lies roughly perpendicular to the filament axis. The myosin head (S1) approaches the actin filament tangentially, the major interaction being with the outermost domain of actin. To distinguish the position of tropomyosin unambiguously in our map, we compared the maps from decorated thin filaments with those from decorated actin filaments. Our difference map clearly shows a peak corresponding to the position of tropomyosin; tropomyosin is bound to the inner domain of actin just in front of the myosin binding site at a radius of about 40 A. As a first step toward looking at the actomyosin structure in a state other than rigor, we examined S1 crosslinked to actin filaments by the zero-length crosslinker EDC in the presence of ATP and after pPDM bridging of the reactive thiols of S1. S1 molecules of the crosslinked complexes in the presence of ATP and after pPDM treatment appear dramatically different from those in rigor. The S1s appear more disordered and no longer assume the characteristic rigor 45[degree sign] angle with the actin filaments. http://www.sciencedirect.com/science/article/B6T3S-47MJHMB-18/2/35096a64cf1102dd0d3597e7652c0c90

400. Flugge, U. I. (1985). Hydrodynamic properties of the Triton X-100-solubilized chloroplast phosphate translocator. *Biochimica et Biophysica Acta (BBA) - Biomembranes* 815: 299-305.
Chem Codes: Chemical of Concern: PSM Rejection Code: IN VITRO.

The molecular weight of the phosphate translocator isolated from spinach envelope membranes was measured in the nonionic detergent Triton X-100. The Stoke's radius of the protein-detergent complex was estimated by gel filtration. The partial specific volume was estimated by equilibrium centrifugation and by differential sedimentation in sucrose gradients containing H2O and 2H2O and the sedimentation coefficient was estimated from the same centrifugation experiments. The phosphate translocator-Triton X-100 complex has an apparent molecular weight of 177 500. Its high partial specific volume (0.86 cm3/g) suggests that bound detergent contributes significantly to the mass. Correcting for the bound detergent (1.9 g/g protein), a molecular weight of 61 000 for

the protein moiety of the complex was calculated. These results suggest that the isolated phosphate translocator exists as a dimer. The shape of the dimer is described as a prolate ellipsoid of revolution with semiaxes calculated to be 6.59 and 1.59 nm in length. Nicolato, Antonio, Piovan, Enrico, Zampieri, Piergiuseppe, and Lonardi, Stefano (1996). Shape recovery and volume calculation from biplane angiography in the stereotactic radiosurgical treatment of arteriovenous malformations. *International Journal of Radiation Oncology*Biology*Physics* 35: 565-577.
Chem Codes: Chemical of Concern: PSM Rejection Code: MODELING.

: A model for calculating the three-dimensional volume of arteriovenous malformations from biplane angiography. : Three-dimensional (3D) volume reconstruction is easily feasible with axial, coronal, or sagittal computer tomography (CT) and nuclear magnetic resonance (NMR) scans. On the other hand, radiosurgicals treatment of arteriovenous malformations (AVM) is exclusively based on two orthogonal stereotactic projections, obtained with angiographic procedures. Most commonly, AVM volumes have been calculated by assimilating the nidus volume to a prolate ellipsoid. We present an algorithm dedicated to 3D structure reconstruction starting from two orthogonal stereotactic projections. This has been achieved using a heuristic approach, which has been widely adopted in the artificial intelligence domain. : Tests on phantom of different complexity have shown excellent results. : The importance of the algorithm is considerable. As a matter of fact: (a) it allows calculations of complex structures far away from regular ellipsoid; (b) it permits shape recovery; (c) it provides AVM visualization on axial planes. Chem Codes: Chemical of Concern: PSM Rejection Code: CHEM METHODS.

The dynamics of prolate spheroidal particles are examined in relation to collisions with a 30 [mu]m radius collector droplet. The rotations of the particles along their trajectories are determined for different particle aspect ratios. The initial particle orientation and position with respect to the collector and the particle rotational inertia are found to have strong influences on the collision efficiencies. Large differences in efficiency can occur for particles if the aerodynamic size is defined at different particle orientations. Capture of prolate spheroidal particles on the downstream side of the collector can occur in the absence of attractive forces in contrast to the case of spherical particles. http://www.sciencedirect.com/science/article/B6V6B-4887W9T-5J/2/3a3cbceeb578a87f2910f2bfeb1fcee2

Chem Codes: Chemical of Concern: PSM Rejection Code: FATE.

Ion concentrations in water collected within a hardwood forest at Turkey Lakes Watershed, Ont. (Lat. 47[degree sign] 03'N, Long. 84[degree sign] 15'W) were examined in relation to those in precipitation at the watershed and at other places in eastern Canada. The mean annual concentration of Ca2+, Mg2+, K+, Na+, H+, NH4+, NO3-, SO42-, Cl- and HCO3- in precipitation, throughfall, forest floor percolate and mineral soil solution were evaluated, and the annual flux of H+, NO3-, SO42- and base cations was calculated. The annual input of cations by bulk precipitation was only a small proportion (17%) of the flux collected below the forest floor. The deposition of SO42- and NO3- in bulk precipitation accounted for 85 and 45%, respectively, of the forest floor fluxes of these ions. The annual flux of H+ in throughfall was less than that in precipitation. Calcium and Mg2+ concentrations in soil solution were highly correlated (P = 0.05) with NO3- during the dormant season and Ca2+ was highly correlated with SO42- during the growing season. Both SO42- and NO3- were largely unreactive with minerals in the Turkey Lakes soil and therefore play a dominant role in cation movement through the soil.

406. France, Richard M., Sellers, Debra S., and Grossman, Steven H. (1997). Purification, Characterization, and Hydrodynamic Properties of Arginine Kinase from Gulf Shrimp (Penaeus aztecus). *Archives of Biochemistry and Biophysics* 345: 73-78.
Chem Codes: Chemical of Concern: PSM Rejection Code: IN VITRO.

Arginine kinase from the tail muscle of the Gulf shrimp (Penaeus aztecus) was purified to apparent homogeneity, using a rapid, high-yield method. The protein exhibits a molecular weight of 40 kDa according to the methods of gel filtration and gel electrophoresis in sodium dodecyl sulfate, also indicating that arginine kinase from shrimp is a monomer. The amino acid content of arginine kinase from shrimp is similar to arginine kinases from several species and to creatine kinase from rabbit muscle. Arginine kinase derivatized at the reactive sulfhydryl with 2-(4'-(iodoacetamido)anilino)naphthalene-6-sulfonic acid exhibits significant changes in fluorescence anisotropy only in the presence of the guanidino substrate and the so-called "dead-end complex" containing arginine + MgADP. Several compounds structurally similar to arginine, e.g., ornithine do not interact with arginine kinase, suggesting a narrow specificity for substrate binding. The most suitable description of the decay of the fluorescence of arginine kinase derivatized with 5-[(((acetyl)-amino)ethyl)amino]naphthalene-1-sulfonate (AEDANS-AK), from among discrete and distributed models, is a triple exponential discrete decay. The presence of the dead-end complex only marginally increases the rate of decay, but significantly shifts the magnitude of the preexponentials (amplitudes) between the two major decay components. One interpretation of these results is that multiple conformational isomers may occur, in which the relative concentrations are dependent upon the presence of the dead-end complex. Measurement of the time-dependent anisotropy decay of AEDANS-AK reveals a two-term decay law with rotational correlation times of 0.88 and 15.2 ns. The slower component is close to the theoretical value of 16.7 ns for an isotropic rotator of the molecular mass of arginine kinase. This finding suggests that the overall conformation of arginine kinase may differ considerably from the prolate ellipsoidal subunits of the functionally analogous creatine kinase. arginine kinase; purification; fluorescence; characterization; conformation http://www.sciencedirect.com/science/article/B6WB5-45MH0PS-65/2/fb48d84b12293a97ab9c5a19433b441e

Three (1%) contained residues above the max. residue limits (MRL) permitted under the Canadian Food and Drug Act and regulations; two involved phosalone at 5.9 and 6.2 mg/kg resp. and one involved diphenylamine at 6.7 mg/kg when the MRL was 5.0 mg/kg for both compds. Low residues of dicofol, endosulfan, phosalone, phosmet, captan, daminozide, and diphenylamine were frequently found; however they were well below the MRLs. These residue levels were correlated with survey data on the areas of the apple crop treated with specific pesticides. Residues of carbaryl, diazinon, ethion, azinphosmethyl, parathion, and dithiocarbamate fungicides were found occasionally; all were well below the MRLs and correlated with the pattern of use. No residues of PCB were found to a limit of detection of 0.01 mg/kg. [on SciFinder (R)] 0265-203X apple/ pesticide/ Canada

All samples were analyzed for insecticides and fungicides. The anal. procedure included tests for Cl-contg., P-contg., synthetic pyrethroid, and methylcarbamate insecticides and dithiocarbamate, dicarboximide, and Cl-contg. fungicides. The commodities tested involved apples, blueberries, cherries, grapes, peaches, pears, raspberries, and strawberries. In 14% of all fruit samples, pesticide residues were below the detection limits of 0.005-0.02 mg/kg. A further 14% had total combined pesticide residues <0.1 mg/kg. Total combined fungicide and insecticide residues were 0.1 to 11 mg/kg in 72% of the samples. Six pesticides were in violation of max. residue limits (MRL) on 11 (3.6%) of the samples. Captan exceeded the 5 mg/kg MRL in 5 samples and EBDC exceeded the 7 mg/kg MRL in 2. Other violations included single fruit samples with dicofol, endosulfan, phosalone, and iprodione above the MRL. Raw grapes harvested for wine contained residues of 10 pesticides and the no. changed little following the crushing of the grapes; however, fermn. into wine significantly reduced residues. Six insecticides and 4 fungicides were present on the raw grapes and 4 of 105 samples had concns. above the MRL. Following crushing, 4 insecticides and 5 fungicides were identified and 4 of 40 samples had concns. above the MRL. In wine, only 3 insecticides were identified and all were well below the MRL. Carbaryl appeared to be the most persistent, declining very little between raw grapes and wine. [on SciFinder (R)] 0265-203X fruit/ insecticide/ fungicide;/ wine/ insecticide/ fungicide

Role: BIOL (Biological study) (of vegetables grown in Ontario) Between 1986 and 1988, 433 composite vegetable samples representing 16 commodities were collected from farm deliveries to the marketplace in Ontario, Canada. All samples were analyzed for insecticides and fungicides. The analyses included organochlorine, organophosphorus, synthetic pyrethroid, and N-methylcarbamate insecticides and dithiocarbamate, dicarboximide, and organochlorine fungicides. The commodities tested included asparagus, beans, carrots, celery, cole crops, cucumbers, lettuce, onions, peppers, potatoes, radishes, rutabagas and tomatoes. In 64% of the samples, no pesticide residue were identified to the limits of detection which ranged from 0.005 to 0.05 mg/kg. A further 22% had combined insecticide and fungicide residues below 0.1 mg/kg. Most of the pos. findings were a fraction of the Maximum Residue Limit permitted for each commodity under the Canadian Food and Drugs Act and Regulation. Three samples (0.7%) had residues that exceeded the MRL. These involved diazinon and parathion on celery and chlorothalonil on peppers. While some commodities had no detectable residues others had measurable residues of up to three sep. pesticides. The most were found on celery, lettuce and field tomatoes. BIOL (Biological study) (of peaches and strawberries and sweet cherries, of Canada); 94-74-6 (MCPA) Role: BIOL (Biological study) (of peaches and strawberries, of Canada); 115-32-2 (Dicofol); 732-11-6 (Phosmet) Role: BIOL (Biological study) (of peaches and sweet cherries, of Canada); 56-38-2 (Parathion); 86-50-0 (Azinphosmethyl) Role: BIOL (Biological study) (of peaches, of Canada); 60-51-5 (Dimethoate); 72-43-5 (Methoxychlor); 101-05-3 (Anilazine); 1563-66-2 (Carbofuran); 2439-10-3 (Dodine) Role: BIOL (Biological study) (of strawberries, of Canada); 63-25-2 (Carbaryl) Role: BIOL (Biological study) (of sweet cherries and peaches, of Canada); 94-75-7 (2,4-D) Role: BIOL (Biological study) (of sweet cherries and strawberries, of Canada); 72-55-9 (DDE); 1897-45-6 (Chlorothalonil) Role: BIOL (Biological study) (of sweet cherries, of Canada) Sweet cherries, peaches, and strawberries grown in Ontario Canada in 1980-1984 were monitored for compliance with the max. residue limit (MRL) for approved insecticides, fungicides and herbicides. Residues of carbaryl, dicofol, endosulfan, phosalone, phosmet, captan, chlorothalonil, and 2,4-D were found in many of the 36 sweet cherry samples, and none exceeded the MRL. The limit of dicofol and azinophosmethyl were in violation of the MRL in each of 2 of 26 peach samples. In 36 peach samples, and within the MRL, endosulfan, parathion, phosmet, carbaryl, captan, and MCPA were obsd. In 107 strawberry samples, 1 exceeded the MRL for captan and a second exceeded the MRL for carbofuran. Other pesticides on strawberries, but below the MRL, were endosulfan, dimethoate, 2,4-D and MCPA. Although anilazine, dodine, azinophosmethyl, and methoxychlor had also been applied to strawberries, none of these pesticides were detected in the fruit. ABSTRACT: BIOSIS COPYRIGHT: BIOL ABS. Water samples were collected from the mouths of the three major agricultural watersheds, the Grand, the Saugeen, and the Thames (Ontario, Canada), between January 1986 and December 1990. Analyses were performed for 18 herbicides, 26 insecticides, and 4 fungicides in use in the basins. A total of between 425 and 474 samples were analyzed for each of the major groups of pesticides. Six herbicides, two insecticides and polychlorinated biphenyls (PCBs) were identified in surface water. Atrazine and its metabolite desethylatrazine were the most frequently found pesticide present in 340 of 474 samples or 72%; the metabolite was not always present with the parent compound. The second most frequently found pesticide was metolachlor which was identified in 30 of 474 samples or 6.3%. 2,4-D and cyanazine were present in 3.3% and 1.5% of the samples, respectively; alachlor, mecoprop, and simazine were present in 0.5% of the samples. Dicamba and metribuzin were present in single sam

This involved the analyses of water from 359 wells where the suspected contamination originated from spills, spray drift, or surface runoff waters carrying pesticides into wells. Investigations covered 83 spill events involving 104 rural wells; tests showed 79 of these became contaminated. The contaminations were caused by spills of pesticide concs., back-siphoning of spray solns., and/or spills from overfilling, emptying or rinsing spray equipment. The pesticides either entered directly into the wells or contaminated the area in the vicinity of the wells. In spite of cleanup attempts, difficulty was experienced in decontaminating most well waters and some had to be abandoned. The longest period of monitoring a contaminated well was 1117 days; during the time the decline in residue was slow. Investigations were made into 228 events involving 255 wells where spray drift, and/or surface runoff waters with pesticides were obsd. entering the well; however, only 55 contained detectable residues. The highest proportion of these events was assocd. with surface runoff or spray drift from cornfields; of 86 wells involved only 26 contained measurable residues and all involved atrazine [1912-24-9]. Fifty-seven well investigations were assocd. with spraying right-of-ways and 16 waters were contaminated with 2,4-D [94-75-7] and dichloroprop [120-36-5]. The remaining 13 well contaminations were assocd. with various other land-use activities. It required 45 to 347 days to decontaminate these 55 wells. Index Terms: Kinetics of hydrolysis (of organophosphate pesticides); Soils (organophosphate pesticides hydrolysis in, kinetics of); Pesticides (organophosphate, hydrolysis of, in soil and water)
CAS Registry Numbers: 56-38-2; 121-75-5; 732-11-6; 2463-84-5; 2921-88-2; 5598-13-0; 10311-84-9 Role: RCT (Reactant), RACT (Reactant or reagent) (hydrolysis of, in soil and water, kinetics of) The breakdown of several organophosphate pesticides both in aq. soln. and moist soil were investigated. The hydrolysis rates of phosmet [732-11-6], dialifor [10311-84-9], malathion [121-75-5], methyl chlorpyrifos [5598-13-0], dicapthon [2463-84-5], chlorpyrifos [2921-88-2], and parathion [56-38-2] were measured at 20 and 37.5 Deg (pH 7.4) in an aq. system. A similar study was carried out at 20 Deg and pH 6.1. The half-lives at 20 Deg (pH 7.4) range from 7.1 h for phosmet to 130 days for parathion; the corresponding rates at 37.5 Deg are approx. 5 times greater than those at 20 Deg. The rate equations at pH 7.4 were calcd. from the 20 and 37.5 Deg data in an Arrhenius form: k = A(-Ea/RT). In moist soil (pH 6.2), degrdn. rates were measured at pesticide concns. of 1.0 and 0.1 ppm in a Willamette clay loam soil at a moisture level of 50% of field capacity. A comparison of the 20 Deg half-lives for phosmet and dialifor in water and in moist soil at comparable pH indicates an appreciable increase in persistence for these 2 compds., but little for the others in the soil-water system. The stabilities of these agricultural pesticides are discussed. [on SciFinder (R)] 0021-8561 organophosphate/ pesticide/ stability/ water/ soil

The structural similarity of chems. within such groups, suggests that they share a common mode of action (MOA) which is based on their common chem. reactivity. Often, however, a descriptor for this reactivity alone can not explain the obsd. toxicity satisfactory but addn. of a hydrophobicity parameter, like log KOW, is found to improve the relationship. In the present paper, an alternative strategy is proposed and tested with three different literature data sets. Instead of searching for better descriptors to establish a QSAR for the whole data set, the assumption that all compds. within the set act by the same MOA was critically reviewed. We tested the hypothesis that some of the compds. within the data sets acted by narcosis (general anesthesia), a second plausible mode of action in acute fish toxicity. Narcosis potency at obsd. lethal exposure levels was modeled with a baseline toxicity QSAR. The literature data sets were split in a narcosis and a reactive subset and for each of them a sep., one-parameter QSAR was established. For a set of OP-esters, nine out of 20 compds. were identified as possible narcotic compds. and their toxicity could be described with a narcosis QSAR. For the 11 compds. remaining in the reactive subset, a good correlation between acute toxicity and measured, in-vitro AChE inhibition rate was found ($r2 = 0.68$) which would have been overlooked if the whole data set was used. The use of two sep. QSARs instead of one mixed QSAR was also tested for literature data sets of nitrobenzenes and a,b-unsatd. carboxylates. It was shown that for the description of toxicity data of all three groups of reactive compds., a model which uses two sep. modes of action was superior to a mixed model which uses a reactivity and a hydrophobicity parameter in a multiple linear regression. Citations: 32) Anon; Document SANCO/10476/2003 2004 A new anal. strategy for the screening and confirmation/quantification of multiclass pesticide residues in vegetables was established and validated. No complicated sample prepn. was needed, but only a simple and rapid extn. using Et acetate and sodium sulfate, which required no cleanup. The approach is based on the use of the triple quadrupole (QqQ) mass spectrometry (MS) as detection system in gas chromatog. (GC). In a 1st step, a GC-QqQ-MS screening method, which monitors only one MS/MS transition by compd., allows the identification of .apprx.130 pesticides in 11.6 min. In this way, the differentiation between neg. and potentially nonneg. samples is carried out. In the 2nd step, the nonneg. samples are reanalyzed by the GC-QqQ-MS confirmation/quantification method, which monitors 2 or 3 MS/MS transitions by compd. Confirmation of pesticides was based on the comparison of intensity ratios for the main ions in samples with those obtained on the same day from the std. in a matrix contg. the pesticides at a pre-established concn. level. Quantification of the identified and confirmed pesticides was based on the addn. std. method, which avoids matrix effect. The proposed anal. strategy allowed a reliable identification and confirmation of the target pesticides at trace levels, reducing anal. time and increasing sample throughput in routine anal. labs. Chem Codes: Chemical of Concern: PSM Rejection Code: BACTERIA.

ABSTRACT: BIOSIS COPYRIGHT: BIOL ABS. Hemolysin genes of the reference strains of Actinobacillus-pleuropneumoniae serotype 1 and 2 were identified, cloned, and expressed in Escherichia-coli by using polymerase chain reaction amplification with oligonucleotides derived from the DNA sequence of the corresponding appA gene from A. pleuropneumoniae serotype 5. The three genes from serotypes 1, 2, and 5 have identical restriction maps and appear to encode a hemolysin which was previously identified in serotype 2 and designated HlyII. Gene appA is different from hlyIA encoding the major hemolysin type I (HlyI) which was identified earlier in serotype 1. Polymerase chain reaction amplification with oligonucleotides derived from the DNA sequence of hlyIA of serotype 1 showed that the gene encoding Hly1 is present in serotype 1 but not in serotype 2, in contrast to the gene encoding HlyII that was present in both serotypes. This was confirmed by Western blot (immunoblot) experiments using monoclonal antibodies specif

423. Fu, Chi-yu, Morais, Marc C., Battisti, Anthony J., Rossmann, Michael G., and Prevelige, Jr Peter E. (2007). Molecular Dissection of O29 Scaffolding Protein Function in an in Vitro Assembly System. *Journal of Molecular Biology* 366: 1161-1173.
Chem Codes: Chemical of Concern: PSM Rejection Code: VIRUS.

An in vitro assembly system was developed to study prolate capsid assembly of phage o29 biochemically, and to identify regions of scaffolding protein required for its functions. The crowding agent polyethylene glycol can induce bacteriophage o29 monomeric capsid protein and dimeric scaffolding protein to co-assemble to form particles which have the same geometry as either prolate T = 3 Q = 5 procapsids formed in vivo or previously observed isometric particles. The formation of particles is a scaffolding-dependent reaction. The balance between the fidelity and efficiency of assembly is controlled by the concentration of crowding agent and temperature. The assembly process is salt sensitive, suggesting that the interactions between the scaffolding and coat proteins are electrostatic. Three N-terminal o29 scaffolding protein deletion mutants, [Delta] 1-9, [Delta] 1-15 and [Delta] 1-22, abolish the assembly activity. Circular dichroism spectra indicate that these N-terminal deletions are accompanied by a loss of helicity. The inability of these proteins to dimerize suggests that the N-terminal region of the scaffolding protein contributes to the dimer interface and maintains the structural integrity of the dimeric protein. Two C-terminal scaffolding protein deletion mutants, [Delta] 79-97 and [Delta] 62-97, also fail to promote assembly. However, the secondary structure and the dimerization ability of these mutants are unchanged relative to wild-type, which suggests that the C terminus is the likely site of interaction with the capsid protein. bacteriophage o29/ scaffolding proteins/ in vitro capsid assembly/ prolate procapsid http://www.sciencedirect.com/science/article/B6WK7-4MH7TR3-4/2/22b9e89398dfd7175f7c605790ae5741

424. Fujime, Satoru and Kubota, Kenji (1985). Dynamic light scattering from dilute suspensions of thin discs and thin rods as limiting forms of cylinder, ellipsoid and ellipsoidal shell of revolution. *Biophysical Chemistry* 23: 1-13.
Chem Codes: Chemical of Concern: PSM Rejection Code: CHEM METHODS.

A previous formulation of the field correlation function G1([tau]) of light quasielastically scattered from suspensions of rigid rods undergoing anisotropic translational as well as rotational diffusion

(T. Maeda and S. Fujime, Macromolecules 17 (1984) 1157) was extended to the cases of suspensions of cylinders (length L and radius R), ellipsoids and ellipsoidal shells of revolution (x2/b2 + y2/b2 + z2/a2= 1). The present formulation includes that for suspensions of rigid rods in the limit of KR << 1 or in the limit of b/a << 1 and Kb << 1 (an extremely prolate ellipsoid), and also that for suspensions of discs in the limit of KL << 1 or in the limit of b/a >> 1 and Ka << 1 (an extremely oblate ellipsoid), where K is the length of the scattering vector. Explicit forms of G1([tau]), of the first cumulant of G1([tau]) and of the dynamic form factors will be given, and numerical methods suitable for computation of dynamic form factors will be discussed. The present results can be applied to the analysis of experimental data for dilute suspensions of thin rods and thin discs. When the situation is favorable, our method can provide transport coefficients D1, D3, and [Theta] from dynamic light-scattering data only, where D1 and D3 are, respectively, the translational diffusion coefficients parallel with the x (y) and z axes, and [Theta] the rotational diffusion coefficient around the x (y) axis. Solution-state dynamics of sugar-connected spin probes in sucrose solution as studied by multiband (L-, X-, and W-band) electron paramagnetic resonance. *Journal of Magnetic Resonance* 163: 174-181.
Chem Codes: Chemical of Concern: PSM Rejection Code: CHEM METHODS.

A multiband (L-band, 0.7 GHz; X-band, 9.4 GHz; and W-band, 94 GHz) electron paramagnetic resonance (EPR) study was performed for two glycosidated spin probes, 4-([alpha],[beta]--glucopyranosyloxy)-TEMPO (Glc-TEMPO) and 4-([alpha],[beta]--lactopyranosyloxy)-TEMPO (Lac-TEMPO), and one non-glycosylated spin probe, 4-hydroxy-TEMPO (TEMPOL), where TEMPO=2,2,6,6-tetramethyl-1-piperidinyloxyl, to characterize fundamental hydrodynamic properties of sugar-connected spin probes. The linewidths of these spin probes were investigated in various concentrations of sucrose solutions (0-50 wt%). The multiband approach has allowed full characterization of the linewidth parameters, providing insights into the molecular shapes of the spin probes in sucrose solution. The analysis based on the fast-motional linewidth theory has yielded anisotropy parameters of [rho]x [approximate] 2.6 and [rho]y [approximate] 0.9 for Glc-TEMPO, and [rho]x [approximate] 4.2 and [rho]y [approximate] 0.9 for Lac-TEMPO. These values indicate that the glycosidated spin probes have a prolate-type molecular shape elongated along the x-axis (NO[square root] axis) with Lac-TEMPO elongated more remarkably, consistent with their molecular structures. The interaction parameters k (the ratios of the effective hydrodynamic volumes to the real ones) corrected for the difference in molecular shape have been estimated and found to have the relation k(TEMPOL) < k(Glc-TEMPO) [approximate] k(Lac-TEMPO). This agrees with the expectation that glycosidated spin probes can have stronger hydrogen bonding to water. Glycosidated spin probes are expected to be useful for probing sugar-involving interactions, which commonly occur in biological systems. Thus this study will provide an indispensable basis for such spin-probe studies. Chem Codes: Chemical of Concern: PSM Rejection Code: VIRUS, CHEM METHODS.

ABSTRACT: A method for packing soil columns to investigate viral transport phenomena is described. The columns were 10 cm in diameter and ranged from 33 to 100 cm in length. Field conditions of the soil, including bulk density and profile, were reproduced in columns. Ionic gradients resulting from sequential applications of wastewater and distilled water affected the movement of poliovirus I (Chat) through soil. Compared with 33-cm- and 66-cm-length columns, lower concentrations of infectious virions were observed in the percolates from 100-cm soil

columns. These results may be attributed to the greater pore volume in the longer columns (the greater volume of soil contained in these columns), whereas the volume of liquid applied was constant for all columns.

Chem Codes: Chemical of Concern: PSM Rejection Code: SURVEY.

ISSN: 0075-5974
Abstract: The pollen morphology of 14 species, 6 subspecies and 4 varieties of Neuracanthus Nees is described and illustrated with light, scanning and transmission electron microscopy. The pollen is oblate to prolate spheroidal, 3-colporate, tectate fine perforate. It is distinguished by its lack of distinctive features, unusual within the highly eurypalynous family Acanthaceae. The pollen is unlike that of the suggested relatives of Neuracanthus. The genes appears to be palynologically isolated within the family, with relatively unspecialized pollen.

(106) of pesticides and related compds. during the cryogenic sample processing of apples was undertaken. For the 1st time the procedure included an assessment of the losses during the freezing of the fruits, prior to processing. The stability of each pesticide during processing was assessed by comparing the mean recovery for the lab.-spiked samples with the mean \"survival\" of the pesticides in cryogenically processed samples. The results clearly demonstrate that the vast majority, 94 of 106, of pesticides were stable during cryogenic processing. Of particular importance was that losses of several pesticides [bitertanol (95%), heptenophos (50%), isofephos (40%), and tolylfluanid (48%)] reported to occur during ambient processing of apples did not occur during cryogenic processing. Losses of dichlofluanid (54%), chlozolinate (22%), and etridiazole (40%), previously reported to occur during ambient processing of apples, were reduced to barely significant levels (10, 17, and 14%, resp.) by cryogenic processing. Small apparent losses for a few of the compds. were attributable to anal. and sample handling difficulties, rather than to losses during processing, and need further investigation. (HPTLC). These organophosphates were sepd. on plates with three different developing systems within 6-18 min and detected by means of UV radiation and coloring reactions with 4-(4-nitrobenzyl)pyridine-tetraethylenepentamine reagent (NT reagent) or palladium chloride reagent (PdCl2 reagent). Each organophosphate was accurately identified by means of the RF*100 value and the spot color in three systems. The detection limits of dichlorvos, fenitrothion, malathion, methidathion, parathion and trichlorfon in serum by the liq.-liq. extn. method were 1.1, 0.12, 0.12, 0.05, 0.6 and 0.1 mg/mL, resp. These sensitivities may be sufficient to detect those organophosphates in patient serum after acute poisoning. [on SciFinder (R)] 0378-4347 thin/ layer/ chromatog/ insecticide/ blood/ forensic

433. Gallinella, Enzo and Cadioli, Beniamino (1991). Theoretical and experimental study of the non-s-cis form of unsaturated ethers. Molecular structure and vibrational assignment of the high-energy isomer of methylvinylether. *Journal of Molecular Structure* 249: 343-363.
<u>Chem Codes</u>: Chemical of Concern: PSM <u>Rejection Code</u>: CHEM METHODS.

The molecular conformation of the high-energy isomer of methylvinylether has been re-investigated. Ab initio calculations were performed using the 6-31G and 6-31G* bases at the SCF level, accounting for electron correlation by full second- and third-order Moller--Plesset perturbative treatments. The internal potential energy function, as derived from calculations at several torsional angles with complete geometry optimization, indicated the high-energy isomer in a wide double-minimum potential well at a CCOC dihedral angle between 156.7 and 159.4[degree sign] from the most stable s-cis form. At every level the two equivalent minima were scarcely resolved, as expressed by a very low interconversion barrier ranging from 10.8 to 21.7 cm-. Estimates of the skeletal torsional energies in the one-vibration approximation gave aground state energy at or just above the barrier height, thus depicting the high-energy isomer as an effective s-trans form. The IR spectra of the pure liquid and the vapour were taken at several temperatures. In the mid-IR spectrum at medium-high resolution, marked fine rotational structure appeared in almost all of the gas-phase absorption envelopes of both isomers.Four bands attributed to the high-energy isomer were analyzed inthe approximation of a quasi-prolate rotor: one, of a parallel-like type, yielded B+C=0.28-1; the other three, of perpendicular-like type, yielded similar values, 2.38, 2.34 and 2.27 cm-1, for 2[A--(B+C)/2]. Both these molecular parameters agree with those expected for an s-trans conformation or one very near to it. A prediction of the vibrational

spectrum of the high-energy isomer was made from the harmonic force constants derived at the SCF 6-31G* level; the calculated frequencies were corrected by transferring scale factors from the s-cis isomer. With this procedure, the average difference between the eleven observed frequencies and the corresponding predicted frequencies amounted to 4.2 cm-1.

Electron impact (EI)/MS/MS and chem. ionization (CI)/MS/MS were developed for 80 compds., including organochlorine, organophosphorus, organonitrogen, and pyrethroids, providing unambiguous spectral confirmation for these complex matrixes. Residues were extd. from samples with acetone followed by a mixt. of dichloromethane-petroleum ether. Two injections per sample were required for anal. of the entire pesticide list by EI/MS/MS and CI/MS/MS. Initial steps involving cleanup and concn. of exts. were eliminated. The excellent selectivity and good linearity allowed quantification and identification of low levels of pesticides in the most difficult matrixes. The method has been used for routine anal. of many vegetables. [on SciFinder (R)] 1060-3271 pesticide/ GC/ tandem/ MS/ fruit/ vegetable

Citations: 58) Ackermann, H; Arch Toxicol 1976, 36, 127 Phosmet is an organophosphate insecticide, widely used on fruit trees in orchards. There is a potential for occupational and para-occupational exposure to this insecticide. While there is some evidence of a carcinogenic effect, phosmet has not been through a complete review for its carcinogenic potential by the International Agency for Research on Cancer (IARC) or the United States Environmental Protection Agency (EPA). Health effects from phosmet are undergoing a review at the EPA, as part of the procedure for reassessment of tolerances for OP under the Food Quality and Protection Act of 1996 (FQPA). In this evaluation, the authors have used a modification of the IARC approach to conduct a detailed evaluation of any direct or related evidence of cancer risk, with a focus on breast cancer risk from phosmet. The authors have critically evaluated all the available human, exptl. animal, and cancer-related mol. and mechanistic studies on phosmet. Chem. and up-to-date regulatory information is included, as well as a discussion of phosmet's environmental fate and potential for human exposure. Evidence available so far does not indicate that phosmet increases breast cancer risk. It is proposed that phosmet be classified in Group 3 in the Program on Breast Cancer and Environmental Risk Factor's (BCERF) breast cancer risk classification scheme. This group represents chems. that are not classifiable for breast cancer risk in humans. [on SciFinder (R)] 0886-5140 phosmet/ breast/ cancer/ risk/ human/ classification

<u>Chem Codes</u>: Chemical of Concern: PSM <u>Rejection Code</u>: MODELING.

ABSTRACT: BIOSIS COPYRIGHT: BIOL ABS. The studies carried out in Quebec (Canada) in order to document and understand agricultural nonpoint pollution and published recently (1993-1998) are briefly summarized, and discussed with respect to agricultural nonpoint pollution control needs. Publications were requested from most of researchers involved with agricultural nonpoint pollution studies. The current literature was reviewed for papers on the impact of agricultural practices (fertilization, tillage, pesticide use, etc.) on water qua st Management Practices, develop watershed-scale water quality models that can aid in selecting the most efficient field scale solutions and lead to water quality improvements for an entire watershed, and initiate other pilot projects aimed at testing the watershed approach on a wider scale.

437. Garau, M. A., Dalmau, J. L., and Felipo, M. T. (1991). Nitrogen Mineralization in Soil Amended With Sewage Sludge and Fly Ash. *Biol fertil soils* 12: 199-201.
Chem Codes: Chemical of Concern: PSM Rejection Code: FATE.

ABSTRACT: BIOSIS COPYRIGHT: BIOL ABS. The effect of fly ash on N mineralization in sewage sludge was studied during a 5-week aerobic incubation of soil-waste mixtures at different loading rates under controlled conditions. Periodically, the mixtures were leached with distilled water and the inorganic N released was determined in the percolates. The data were tested by an analysis of variance with repeated measures. Significant differences were found among different incubation periods and also between different treatments. The net N mineralization, expressed as a percentage of organic N added in the sludge, was drastically reduced when higher rates (500 Mg ha-1) of flay ash were added.

Citations: 25) Currie, L; Anal Chim Acta 1999, 391, 105 A method for the multiresidue anal. of olive oil samples for 26 pesticides is proposed. Residual pesticides are extd. from oil using an n-hexane/acetonitrile mixt., exts. being cleaned-up by gel permeation chromatog. (GPC) for anal. by gas chromatog.-tandem mass spectrometry (GC-MS/MS). Electron ionization and chem. ionization are employed in a single anal. for the detn. of pesticides. Pesticide recoveries from virgin and refined olive oil spiked with 10, 100 and 250 mg/kg concns. of the pesticides ranged from 83.8 to 110.3%. The proposed method features good sensitivity: its limits of quantification are low enough to allow pesticide residues to be detd. at concns. below the max. residue levels legally accepted. The precision, expressed as relative std. deviation, ranges from 4.93 to 8.11%. Applicability was tested on 40 olive oil samples. Several pesticides were detected in most of the virgin olive oil samples. By contrast, refined olive samples contained few pesticides, and only endosulfan sulfate was detected in all. ABSTRACT: The inclusion of phytase in monogastric animal feed has the benefit of hydrolyzing indigestible plant phytate (myo-inositol 1,2,3,4,5,6-hexakis dihydrogen phosphate) to provide poultry and swine with dietary phosphorus. An ideal phytase supplement should have a high temperature tolerance, allowing it to survive the feed pelleting process, a high specific activity at low pHs, and adequate gastric performance. For this study, the performance of a bacterial phytase was optimized by the use of gene site saturation mutagenesis technology. Beginning with the appA gene from Escherichia coli, a library of clones incorporating all 19 possible amino acid changes and 32 possible codon variations in 431 residues of the sequence was generated and screened for mutants exhibiting improved thermal tolerance. Fourteen single site variants were discovered that retained as much as 10 times the residual activity of the wild-type enzyme after a heated incubation regimen. The addition of eight individual mutations into a single construct (Phy9X) resulted in a protein of maximal fitness, i.e., a highly active phytase with no loss of activity after heating at 62 degrees C for 1 h and 27% of its initial activity after 10 min at 85 degrees C, which was a significant improvement over the appA parental phytase. Phy9X also showed a 3.5-fold enhancement in gastric stability.

<u>Chem Codes</u>: Chemical of Concern: PSM <u>Rejection Code</u>: CHEM METHODS.

The utility of the boundary element technique is demonstrated on the problem of linear chains of spheres translating and rotating through a quiescent fluid. The method takes advantage of the linearity of the problem by using superposition of the general solution for the flow generated by point forces on the bounding surfaces of the fluid to satisfy the boundary conditions. The BEM results for translational drag of chains of spheres compare very well with published experimental and computational data. We also show that slender body theory provides an approximate analytic result that is useful in interpreting and correlating the BEM calculations. Slender body theory also revealed that the model of the particle as a single prolate spheroid with equal aspect ratio produced a result equal to that for the chain of spheroids correct to second order, while the model of the chain as a cylinder produced an upper bound on the drag. Slender body theory also gives a reasonable estimate for the rotational resistance for chains, which, together with the BEM results, are reported here for the first time. http://www.sciencedirect.com/science/article/B6V6B-

Chem Codes: Chemical of Concern: PSM Rejection Code: CHEM METHODS.

A computationally-efficient method is presented to calculate local particle concentration enhancements resulting from potential fluid flow around an idealized aircraft fuselage and wing. The geometries chosen for study are a 10:1 prolate ellipsoid at 0[degree sign] angle of attack and a Joukowski airfoil at 0[degree sign] and 5[degree sign] angles of attack, for which potential flow analytic solutions are known. The collection efficiency of and surface concentration on a cylinder in potential flow are also considered for algorithm verification. Particle concentration is calculated along particle pathlines by a mixed Eulerian-Lagrangian technique developed by Fernandez de la Mora and Rosner (1981, Fernandez de la Mora, J. F. and Rosner, D. E., Physico Chem. Hydro. 2, 1). Ordinary differential equations for particle position, velocity, and concentration are integrated numerically by a variable order, backward difference algorithm. The calculations show the creation of regions of increased concentration near objects, and of particle-free shadow zones downstream. The magnitudes of the concentration disturbances are greatest at intermediate Stokes numbers (0.1-1.0) where inertia and drag are equally dominant. Samplers placed in these regions of enhanced particle concentration may not provide accurate concentration measurements. Ultimately, this approach could be included with detailed flow solutions about specific aircraft geometries to provide guidance in locating samplers in regions of acceptably small concentration deviations. http://www.sciencedirect.com/science/article/B6V6B-488Y43D-2P/2/6ca093e24e18b36746519bedba0902e9

ABSTRACT: BIOSIS COPYRIGHT: BIOL ABS. Leaching by percolation waters of toxic pollutants from solid wastes in a landfill occurs in a substantially different way to that suggested by elution tests in batch agitated reactors. Effective release, in fact, is influenced by two important aspects that distinguish it from the reference standard: gradual removal of the pollutant and hence a possible change in the matrix; the chemical and physical characteristics of the percolation liquid itself, as determined by the acid or basic nature of the wastes. The composition of the percolate from an industrial waste landfill was evaluated to determine the validity of these general considerations. It was found interesting to correlate the composition of the wastes with the transfer of metals and organic substances to the percolating liquids, this being derived from both the flow of rainwater and the expulsion of interstitial liquid present in the wastes. The discrepancy between the real washout and its simulation by a labora

ABSTRACT: Pollution of surface and groundwater by pesticides is an increasing problem that needs to be addressed by the authorities as well as by the farmers themselves. Nowadays, some researchers are considering the numerous small spillages at the farm sites as a relevant entry route to be taken into account for predicting surface and groundwater pollution. In order to tackle this problem, several solutions exist for limiting the disposal of pesticide wastes into the environment. One such system is biopurification of farm wastes by biobed, biofilter or phytobac. In this study, the results of pesticides retention by biofilters under outdoor conditions are presented. The biofilters were filled with a mixture of a soil + peat constituent (25% by volume for each of them) and the rest (50%) with straw or with composted manure ot with chitin (in this later case at the rate of 5 g chitin per liter of substrate). The soil + peat constituent was made either of a material already challenged by pesticides (= recycled biofilters) or of untreated material (new biofilters). Selected pesticides (atrazine, carbofuran, chloridazon, chlortoluron, cyanazine, isoproturon and lenacil) were applied onto biofilters and the eluates were collected and analyzed. Two successive injections of pesticides into the biofilters were conducted. After the first pesticides application, the recycled biofilters made of soil + peat previously treated with pesticides had better retention and degradation rates than the new biofilters. Adding manure also improved these properties of biofilters. Columns made of unchallenged soil + peat and straw (new biofilters) were the least satisfactory: up to 25% of carbofuran were lost. Biofilters made of unchallenged soil + peat and chitin retained the least lenacil. Atrazine was the most retained by biofilters (either new or recycled) with added chitin. Cyanazine was almost absent in the percolates of all biofilters. After the second application of carbofuran and isoproturon, all biofilters improved to the point where (with the exception the new biofilters made of chitin) they retained the totality of the pesticides.

ABSTRACT: TD3: The Lubbock Land Treatment System Research and Demonstration Project, funded by Congress in 1978 (H.R. 9375), was designed to address the various issues concerning the use of slow rate land application of municipal wastewater. The project involved the (1) physical expansion of overloaded 40 year old Lubbock slow rate land treatment system; (2) characterization of the chemical, biological and physical conditions of the ground water, soils and crops prior to and during irrigation with secondary treated municipal wastewater; (3) evaluation of the health effects associated with the slow rate land application of secondary effluent and (4)

assessment of the effects of hydraulic, nutrient and salt mass loadings on crops, soil and percolate. Final rept. 27 Nov 78-31 Dec 85, See also PB86-173622. Prepared in cooperation with Southwest Research Inst., San Antonio, TX., Illinois Univ. at Chicago Circle, and Texas Univ. at San Antonio. Sponsored by Robert S. Kerr Environmental Research Lab., Ada, OK.

448. Gerber, Bernard R., Routledge, Lewis M., and Takashima, Shiro (1972). Self-assembly of bacterial flagellar protein: Dielectric behavior of monomers and polymers. *Journal of Molecular Biology* 71: 317-323.
Chem Codes: Chemical of Concern: PSM Rejection Code: BACTERIA.

The temperature dependence for the dielectric dispersion of the flagellar protein of Salmonella abortus-equi in monomer and polymer form were compared over the frequency range of 50 Hz and 20 MHz. At 20 [degree sign]C the critical frequency and corresponding dielectric relaxation time [tau] of the monomer (mol. wt. [congruent with] 4 x 104) are 520 kHz and 310 nsec; the values of these parameters for the polymer (mol. wt.> = 11[middle dot]1 x 106) are 1[middle dot]1 kHz and 140 [mu]sec. The dielectric behavior of flagellar proteins can be related to orientation in the field of a permanent dipole on the proteins. Graphs of - log ([tau]) versus1/T are linear and the Arrhenius activation energy for disorientation of polymer is 2[middle dot]8 kcal./mole. Two limiting values of this parameter are observed, however, for the monomer: 6[middle dot]2kcal./mole at temperatures below 26 [degree sign]C and 8[middle dot]4 kcal./mole above 35 [degree sign]C. The two values are related to the polymerizable and inactive conformational isomers first reported by Gerber & Noguchi (1967). Nevertheless, the dimensions of the two isomers are remarkably similar. Below 26 [degree sign]C flagellin can be hydrodynamically approximated by a prolate ellipsoid with an axial ratio of 9 : 1 and with a dipolar angle between 30 and 40 [degree sign]; above 35 [degree sign]C the axial ratio decreases slightly to a value of 8 : 1. The dipole moment of the monomer is calculated as 860 Debye; the dipole moment of a monomer in the polymer is less than 150 Debye. Furthermore, the polymer dipole is in its long axis. To account for this result a model is proposed for the helical arrangement of distally-tilted asymmetric monomers to form a tubular flagellum. Such a filament, consequently, will contain an inherent polarity in agreement with observations by others that (1) in vitro growth of the flagellum is unidirectional and (2) that the distal end of the flagellum has a notched or fish-tail appearance. Generally, the polarization of proteins is due primarily to a permanent and not an induced dipole, which arises from fixed charges on the surface of the protein. This type of dipole has two properties useful to self-assembly mechanisms: first, they are vector quantities and so specify direction (bond angle); and second, they are capable of long-range interactions. A survey of the literature shows that for all polymerizable proteins studied, the dipole moment is greatly decreased on forming a polymer. This suggests that a principle of dipole neutralization plays an important role in the self-assembly of proteins. http://www.sciencedirect.com/science/article/B6WK7-4DNGV2N-1G/2/c52afec703eb7c81dc8d8d23f65b5691

452. Ghaly, R. A., Pyke, J. B., Ghaly, A. E., and Ugursal, V. I. (1999). Remediation of Diesel-Oil-Contaminated Soil Using Peat. *Energy sources* 21: 785-799.
Chem Codes: Chemical of Concern: PSM Rejection Code: FATE.

ABSTRACT: BIOSIS COPYRIGHT: BIOL ABS. We investigated a remediation process for

diesel-contaminated soil, in which water was used to remove the diesel from the soil and peat was used to absorb the diesel layer formed on the surface of the water. The percolation of water through the soil was uniform. The time required for water to percolate the soil and for the layers (soil, water, and diesel) to separate depended on the soil depth. Both the depth of soil and mixing affected the thickness of the diesel layer and thus diesel revovery ontent of the diesel-contaminated peat is much higher than that of coal, and the moisture content iswithin the range recommended for biomass gasification.

Citations: Szefe, P; Environ Pollut 2002, 120, 423 Samples of honeybees (Apis mellifera, n = 92) from 14 beehive monitoring stations located in 3 townships in the province of Bologna were analyzed from Apr. to Oct. 2000. The concn. of 32 organophosphorus pesticides and 5 carbamates was detd. through liq.-liq. extn. followed by gas chromatog. with a nitrogen-phosphorus detector and liq. chromatog. coupled to mass spectrometry using atm. pressure chem. ionization in pos. and neg. ion modes. The most contaminated samples were from Granarolo Emilia where cereals (wheat, sorghum, and corn), sugar beets, and potatoes are the main agriculture products. Thirty-five pesticides were detected, with organophosphorus being the most abundant ones. Malathion was detected in 58 of the samples (mean level 0.360 mg/kg) followed by fenithrothion in 53 of the samples (mean level 0.544 mg/kg) and pirimiphos Me in 48 of the samples (mean level 0.006 mg/kg). Temporal trends showed that the max. detection frequency occurred in late spring and was assocd. with the use of treatment products and less rainfall. The obtained results demonstrated the feasibility of using honeybees for assessing pesticide exposure in agriculture settings. Patent Application Country: Application: EP
Priority Application Country: US
Priority Application Number: 97-69243
Priority Application Date: 19971211 Disclosed are controlled-release compns. contg. biol. active compds. incorporated into metal oxide glass having a porous matrix which is prepd. by polymg. one or more metal alkoxide monomers, optionally in the presence of a second metal alkoxide monomer. These compns. may be directly incorporated into the locus to be protected or may be applied to a structure in a coating. Thus, tetraethoxy orthosilicate and methyltriethoxy orthosilicate (mole ratio 4:1), 4,5-dichloro-2-n-octyl-3-isothiazolone (5% by wt. of the final product), and water (mole ratio of alkoxide monomers to water 1:2) were combined in a flask and homogenized by adding methanol or ethanol while stirring; then, 8-10 g of 0.01N HCl per mol of metal alkoxide monomer was added to the reaction mixt., which was allowed to polymerize at room temp. for 3-60 days to give a solid organometallic oxide glass contg. the biol. active compd. The cumulative percentages of 4,5-dichloro-2-n-octyl-3-isothiazolone released were 5, 30, 41, 50 and 64% by wt. in 0, 0.5, 2, 31, and 144 h. 455. Girenko, D. B. and Klisenko, M. L. (Regularities of Extraction of Organophosphorus Pesticides From Water. *Khim. Sel'sk. Khoz. 19(5): 58-60 1981 (9 references).*
Chem Codes: Chemical of Concern: PSM Rejection Code: FATE.

ABSTRACT: PESTAB. Distribution coefficients (D) were given for the organophosphorus insecticides Gardona (tetrachlorvinphos), Khostakvik, metaphos (methyl parathion), methylnitrophos, bromophos, Cyanox (cyanophos), Afugan (pyrazophos), carbophos (malathion), phencapton, Cidial (phenthoate), phthalophos (phosmet), Amiphos (DAEP), Anthio (formothion), and phosphamide (dimethoate). Maximal values of D were observed in solvents permitting formation of hydrogen bonds between the solvent molecule and unshared electron pairs in amide or carbonyl groups. Data were presented on the effect of solvent type on extraction of pesticides from water. Aliphatic hydrocarbons extracted amides not more than 35%; solvents forming pi-complexes, up to 50%; the degree of extraction of preparations with polar solvents was 80-95%. The type of solvent had almost no effect on the degree of extraction of organophosphorus pesticides that did not contain groups that facilitate formation of hydrogen and other bonds. Selection of the appropriate pH was also important.

456. Glass, R. L. and Edwards, W. M. (Dicamba in Lysimeter Runoff and Percolation Water.
Chem Codes: Chemical of Concern: PSM Rejection Code: FATE.

ABSTRACT: PESTAB. The postemergence herbicide dicamba was applied at 5.6 kg/ha on May 1, 1974, to Lysimeter Y101C and to an adjacent soil plot (4.1 m2) at the North Appalachian Experimental Watershed at Coshocton, Ohio. An August storm produced runoff that contained 0.23 ppb of dicamba. Dicamba was detected at 1.0 ppb in the percolate water at the 2.4-m depth 11 mo after application. The data are compared with earlier measurements of 2,4,5-trichloro phenoxyacetic acid (2,4,5-T) and picloram found in runoff and percolation water from this lysimeter. The results indicate that the loss of dicamba in runoff and percolate water will not be a source of groundwater pollution. (Author abstract reprinted by permision of the American Chemical Society)

COMMENTS: Comment in: Nat Biotechnol. 2001 May;19(5):415-6 (medline/11329002)
ABSTRACT: We have developed transgenic mouse models to determine whether endogenous expression of phytase transgenes in the digestive tract of monogastric animals can increase the bioavailability of dietary phytate, a major but indigestible form of dietary phosphorus. We constructed phytase transgenes composed of the appA phytase gene from Escherichia coli regulated for expression in salivary glands by the rat R15 proline-rich protein promoter or by the mouse parotid secretory protein promoter. Transgenic phytase is highly expressed in the parotid salivary glands and secreted in saliva as an enzymatically active 55 kDa glycosylated protein. Expression of salivary phytase reduces fecal phosphorus by 11%. These results suggest that the introduction of salivary phytase transgenes into monogastric farm animals offers a promising biological approach to relieving the requirement for dietary phosphate supplements and to reducing phosphorus pollution from animal agriculture.

The nos. of compds. in these models range from 40 (for the alicyclic model) to 144 (for the carboarom. model). As detd. by cross-validation using the leave-one-out, or jackknife, technique, the accuracy of the models in discriminating between teratogens and nonteratogens ranges from 92.4% to 96%. A single overall assessment of exptl. teratogenesis was chosen as the biol. endpoint; taking into account such factors as dosage, maternal toxicity, and affected organ systems remain to be subjects of further studies. 459. Gomelsky, M. and Kaplan, S. (Appa, a Novel Gene Encoding a Trans-Acting Factor Involved in the Regulation of Photosynthesis Gene Expression in Rhodobacter Sphaeroides 2.4.1. *J bacteriol. 1995, aug; 177(16):4609-18. [Journal of bacteriology]: J Bacteriol*.
<u>Chem Codes</u>: Chemical of Concern: PSM <u>Rejection Code</u>: BACTERIA.

ABSTRACT: A new gene, the product of which is involved in the regulation of photosynthesis gene expression in the anoxygenic photosynthetic bacterium Rhodobacter sphaeroides 2.4.1, has been identified. The isolation of this gene, designated appA (activation of photopigment and puc expression), was based on its ability, when provided in extra copies, to partially suppress mutations in the two-component PrrB-PrrA regulatory system. The presence of extra copies of the appA gene in either prrB, prrA, or wild-type strains resulted in an activation of puc::lacZ expression under aerobic conditions. Constructed AppA null mutants did not grow photosynthetically and were impaired in the synthesis of both bacteriochlorophyll and carotenoids, as well as the structural proteins of the photosynthetic spectral complexes. When grown anaerobically in the dark, these mutants accumulated bacteriochlorophyll precursors. The expression of lacZ fusions to several photosynthesis genes and operons, including puc, puf, and bchF, was decreased in the AppA mutant strains in comparison with the wild type. To examine the role of AppA involvement in bacteriochlorophyll biosynthesis, we inactivated an early gene, bchE, of the bacteriochlorophyll pathway in both wild-type and AppA- mutant backgrounds. The double mutant, AppA- BchE-, was found to be severely impaired in photosynthesis gene expression, similar to the AppA- BchE+ mutant and in contrast to the AppA+ BchE- mutant. This result indicated that AppA is more likely involved in the regulation of expression of the bch genes than in the biosynthetic pathway per se. The appA gene was sequenced and appears to encode a protein of 450 amino acids with no obvious homology to known proteins.

460. Gonzales, D. A., Supkoff, D., Fleck, J., Margetich, S., and Echelberry, J. (Environmental Monitoring of the 1986 Apple Maggot Eradication Project in Humboldt and Del Norte Counties. *Govt reports announcements & index (gra&i), issue 11, 1990*.
Chem Codes: Chemical of Concern: PSM Rejection Code: SURVEY.

ABSTRACT: TD3: The 1986 Apple Maggot Eradication Project required use of the insecticide phosmet over large areas in six counties of northern California. The chemical had no previous use on eradication projects in California, was not registered for use on crabapples and had incomplete information on its environmental fate. Therefore, the Environmental Hazards Assessment Program of the California Department of Food and Agriculture was directed to develop a comprehensive monitoring program to evaluate the environmental levels of phosmet and phosmetoxon, a toxic degradation product. The results of the study indicated a general decrease in phosmet and phosmetoxon concentrations over time in the environmental samples collected, and the degradation rate of phosmet in all the types of sampled media was within an acceptable range. Final rept.

Citations: 80) De Clercq, E; In vitro and ex vivo test systems to rationalize drug design and delivery 1994, 108 The unified representation of spectral moments, classic topol. indexes,

quadratic indexes, and stochastic mol. descriptors show that all these mol. descriptors lie within the same family. Consequently, the same prior probability for a successful quant. structure-activity relation (QSAR) may be expected irresp. of which indexes are selected. Herein, we used stochastic spectral moments as mol. descriptors to seek a QSAR using a database of 221 bioactive compds. previously tested against diverse RNA viruses and 402 nonactive ones. The QSAR model thus obtained correctly classifies 90.9% of compds. in training. The model also correctly classifies a total of 87.9% of 207 compds. on addnl. external predicting series, 73 of them having anti-RNA-virus activity and 134 nonactive ones. In addn., all compds. were regrouped into five different subsets for leave-group-out studies: (1) anti-influenza, (2) anti-picornavirus, (3) anti-paramyxovirus, (4) anti-RSV/anti-influenza, and (5) broad range anti-RNA-virus activity. The model has retained overall accuracies of about 90% on these studies validating model robustness. Finally, we exemplify the practical use of the model with the discovery of compds. 124 and 128. These compds. presented MIC50 values = 3.2 and 8 mg/mL against respiratory syncytial virus (RSV) resp. Both compds. also have low cytotoxicity expressed by their Minimal Cytotoxic Concns. >400 mg/mL for HeLa cells. The present approach represents an effort toward a formalization and application of mol. indexes in bioorg. and medicinal chem. 462. Gonzalez, M., Roca, P., Sainz, F., and Alemany, M. (1982). The estimation of avian egg surface area. A comparison of different methodological approaches. *Comparative Biochemistry and Physiology Part A: Physiology* 73: 101-103.
Chem Codes: Chemical of Concern: PSM Rejection Code: MODELING.

1. 1. Five methods for egg surface area determination have been presented and applied to house sparrow, rock dove, domestic fowl, goose and ostrich eggs. The data were compared with a direct measurement integration of small tronchoconic segments measured from the photographic egg profiles. 2. 2. A very good fit was that of surface area estimation of the shell from its weight, density (thus volume was calculated) and thickness. The best method was a modification of this one corrected by egg volume and shell thickness. 3. 3. Simple mathematic models such as the sphere (with a volume equal to that of the egg) and a prolate spheroid gave poor fits for all samples studied. 4. 4. The computation of the surfaces of two paraboloids joined at their bases calculated by a regression method from the photographic profiles of the eggs gave better results, but nevertheless inferior to those found with the shell parameters methods.

Chem Codes: Chemical of Concern: PSM Rejection Code: HUMAN HEALTH.

ABSTRACT: BIOSIS COPYRIGHT: BIOL ABS. A 51 year old man developed progressive cranial and proximal muscle weakness, hyperreflexia and mental change. The disorder progressed over 9 days following the fifth weekly spraying with the organophosphate (OP) insecticide, phosmet, with limited symptoms of acute toxicity. Marked decremental responses of 50-80% on slow and fast rates of stimulation were improved to 15% by edrophonium or neostigmine. Intracellular recordings at the endplate region of intercostal muscle revealed small miniature endplate potentials (mepps), reduced mean acetylcholine sensitivity and normal membrane potentials. Electronmicroscopy revealed degeneration and regeneration of the endplates. This study demonstrates that OP poisoning due to phosmet can produce a subacute postsynaptic neuromuscular syndrome without marked symptoms of acute toxicity.

ABSTRACT: PESTAB. The selectivity of the thin-layer chromatographic detection and determination of TMC-3 was studied in cadaverous materials in the presence of other organophosphorus pesticides and medicinal preparations. Extraction is done with hexane in the presence of anhydrous sodium sulfate. The extract is first cleaned by redistribution in the hexane-dimethylformamide system, and then by thin-layer chromatography on KSK silica gel in a 5:3 ratio of cyclohexane and chloroform. Following elution with chloroform, the pesticide is identified by thin-layer chromatography, using KSK silica gel layer and a 5:3 ratio of cyclohexane and chloroform as a solvent system. The chromatogram is visualized with palladium reagent or 4-aminoantipyrine. The method is selective and specific for TCM-3 in the presence of anthio, butyphos, diazinon, dursban, carbophos, koral, methylmercaptophos, sayphos, dimethoate, phosaline, phthalophos, and cideal, as well as of the medicinal preparations thiophosphamide, thiodepine, phenothiazine, chloropromazine, isopromethazine, aminazine, mepazine, levomepromazine, disulfiram, and TMTD. Ronnel interferes with the determination.

Chem Codes: Chemical of Concern: PSM Rejection Code: CHEM METHODS.

ABSTRACT: PESTAB. The selectivity and specificity was studied of a thin-layer chromatographic method for the determination of dimethoate (rogor, phosphamide). Following extraction with acidulated water and subsequent extraction with chloroform, the sample was applied on silicic acid layer in benzene, and development was done with a hexane-dioxane mixture at a ratio of 1:1. In the case of cadaverous materials, it was possible to detect dimethoate in the presence of butyphos, gardona, diazinon, dursban, coumaphos, metaphos, methylnitrophos, methylethylthiophos, octamethyl, sayphos, trichlorometaphos-2, phthalophos, phosalone, and and ciodrin. Additional reactions made it possible to detect dimethoate in the presence of trichlorfon and technical grade methylmercaptophos and naled. Quantitative isolation from technical preparations of anthio and carbophos was not possible.

Citations: 25) Bessen, R; J Virol 1992, 66, 2096 Chronic (2 day) exposure of human neuroblastoma cells to the organophosphate pesticide phosmet induced a marked concn.-dependent increase in the levels of PrP present on the cell surface as assessed by biotin labeling and immunopptn. Levels of both phospholipase C (PIPLC)-releasable and non-releasable forms of PrP were increased on the plasma membrane. These increases appear to be due to post-transcriptional mechanisms, since PrP mRNA levels as assessed by Northern blotting were unaffected by phosmet treatment. These data raise the possibility that phosmet exposure could increase the susceptibility to the prion agent by altering the levels of accessible PrP. Chem Codes: Chemical of Concern: PSM Rejection Code: CHEM METHODS.

ABSTRACT: PESTAB Studies were done on the effects of industrial processing operations on the reduction of the phthalophos residue level in apples during production of canned apple sauce as baby food and the effects of deep-freezing on the phthalophos residue dynamics in carrots, cabbage, and beets. In the apple sauce canning technology, blanching, crushing, and sterilization reduced the phthalophos residue level 51%, 28%, and 16-25%, respectively. Deep-freezing even for a prolonged time resulted in neglible reduction of the phthalophos level. Vegetables containing phthalophos in excess of the maximum allowable concentration of 0. 25 mg/kg should not be frozen prior to processing.

473. Goto, S. (Analytical Methods of Pesticide Residues Based on the Notification Environmental Agency. Part 1. Insecticides. *Nippon noyaku gakkaishi (j. Pestic. Sci.) 3(2): 169-178 1978 (9 references).*
Chem Codes: Chemical of Concern: PSM Rejection Code: CHEM METHODS.

ABSTRACT: PESTAB. Although the presence and measuring methods of pesticide residues are regulated by the Food Hygiene Act in Japan, the number of pesticides covered by this law is only 24. Pesticide residues which were not standardized by this act are to be soon regulated by the Environmental Agency. Currently 70 pesticides are under study for standardization. This report deals with the insecticides isozanthion, ethion, ethyl thimethon, chlorpyriphos, chlorphenamidime, chloropropiolate, dialifor, dimethoate, tetradifon, benzomate, phosalone, formothion, methomyl, chlorfenethol, o-sec-butylphenyl methylcarbamate, propargite, naled, chlorfenson, chlorfenvinphos, tetrachlorvinphos, dichlorvos, trichlorfon, methidathion, phenthoate, propoxur and phosmet. Methods of determination, also under consideration, are briefly described.

(KOC) of 185 nonionic org. heterogeneous pesticides have been studied searching for quant. structure-property relationships (QSPRs). The chem. description of pesticide structure has been made in terms of some mol. descriptors: count descriptors, topol. indexes, information indexes, fragment-based descriptors and weighted holistic invariant mol. (WHIM) descriptors; these last are statistical indexes describing size, shape, symmetry and atom distribution of mols. in the three-dimensional space. Three new topol. indexes derived from the electrotopol. state indexes of L.B. Kier, et al. (1991) were proposed. Multiple linear regression anal. was performed after previous selection of the descriptors mostly correlated to the response by Genetic Algorithms. The obtained results confirm the capability of the proposed approach to give predictive models for one of the most important partition properties, such as soil sorption coeff. (KOC). Citations: Todeschini, R; Chemosphere 1996, 32, 1527 The partitioning tendency of chems., in this study pesticides in particular, into different environmental compartments depends mainly on the concurrent relevance of the physicochem. properties of the chem. itself. To rank the pesticides according to their distribution tendencies in the different environmental compartments, the authors propose a multivariate approach: the combination, by principal component anal., of those physicochem. properties like org. carbon partition coeff. (Koc), n-octanol/water partition coeff. (Kow), water soly. (Sw), vapor pressure and Henry's law const. (H) that are more relevant to the detn. of environmental partitioning. The resultant macrovariables, the PC1 and PC2 scores here named leaching index (LIN) and volatility index (VIN), are proposed as preliminary environmental partitioning indexes in different media. These two indexes are modeled by theor. mol. descriptors with satisfactory predictive power. Such an approach allows a rapid predetn. and screening of the environmental distribution of pesticides starting only from the mol. structure of the pesticide, without any a priori knowledge of the physicochem. properties. 481. Griffiths, W. D. and Vaughan, N. P. (1986). The aerodynamic behaviour of cylindrical and spheroidal particles when settling under gravity. *Journal of Aerosol Science* 17: 53-65.
Chem Codes: Chemical of Concern: PSM Rejection Code: CHEM METHODS, FATE.

A Timbrell Aerosol Spectrometer was used to size-select several types of airborne polydisperse particles: approximately unit density spheres, `Fiberfrax' glass fibres and oblate spheroid shaped Arthrinium fungus spores by virtue of their settling velocities due to gravity. The spores had a much narrower size distribution than the others. The spheres were used as the basic calibrating material. The aerodynamic behaviour of the glass fibres under viscous conditions (1.2 x 10-2 [less, approximate] Vg [less, approximate] 0.75 cm s-1), was shown by experiment to be best described by representing the fibres either as straight cylindrical particles or prolate spheroids sedimenting in a direction perpendicular to their polar (major) axes. The aerodynamic diameter, [phi]a, of the cylinders is computed by means of Cox's theory, and that of the prolate spheroids by means of either a volume-corrected or a weight-corrected variation of the theory developed by Oseen. In the range 1.2 x 10-2 [less, approximate] Vg [less, approximate] 0.2 cm s-1 (2 [less, approximate] [phi]a [less, approximate] 8 [mu]m) any one of these theories, as well as the orthodox Oseen theory, was found suitable. The aerodynamic behaviour of the Arthrinium spores tested under the same conditions was shown to be the same as that of oblate spheroids sedimenting in directions parallel to their polar (minor) axes; with [phi]a derived through the orthodox Oseen theory.

Chem Codes: Chemical of Concern: PSM Rejection Code: NON-ENGLISH.

ABSTRACT: PESTAB. Changes were found in the anatomy and physiology of young carp after administration of organophosphorus pesticides. The fish were exposed to Metathion E-50 (active ingredient content 43% fenitrothion) at 0.0096 ml/l, Brevinyl E-50 (active ingredient content 50% dichlorvos at 0.051 mg/l or Decemtion P-6 (active ingredient content 6% phosmet) at 191 mg/l aquarium water for 48 hr. Intoxication in the first two cases was manifested by massive vasodilation with venostasis in the gills and impairment of circulation in the respiratory apparatus. Less severe changes were found in the heart, liver, and pancreas. Marked dystrophic changes, especially vacuolation, were observed in the hepatocytes after intoxication with Decemtion. P-6.

Chem Codes: Chemical of Concern: PSM Rejection Code: NON-ENGLISH.

ABSTRACT: PESTAB. Histopathological changes were investigated in young carp (Cyprinus carpio L.) after intoxication with organophosphorus insecticides. Besides a control group, three groups were placed in solutions of the following for 48 hours: metathion E-5 (active ingredient content 43% fenitrothion) 0.096 ml/l; Brenvinyl E-50 (active ingredient content 50% dichlorvos) 0.051 ml/l; and Decemtion P-6 (active ingredient content 6% phosmet) 191 mg/l. Five pieces of Kr-1 were placed in each of the solutions. The group intoxicated with metathion E-50 showed vasodilation of the gill covers with blood congestion and venostasis, and vacuolation of the upper respiratory epithelia and hepatocytes. Insufficient coloring of the pancreatic acinar cells, dilation of renal tubules, and spreading of the myocardium were also found. Vasodilation and venostatis of the gills, damaged respiratory epithelia, vacuolation of the hepatocytes, and fragmentation and sufficient coloring of the musculature were noted in the group intoxicated with Brenvinyl. Necrobiotic changes in the liver cells, vacuolation of renal tubules, dystrophic changes in the upper respiratory epithelia, and vacuolation of the hepatocytes were observed in the group intoxicated with Decemtion P-6.

Abstract: Functional nematocysts of one specific morphological class, the penetrant microbasic mastigophores, were isolated from the sea anemone, Aiptasia pallida. These nematocysts contain a multicomponent venom composed of several proteins, including those with neurotoxic, hemolytic, and lethal activities. Hemolytic activity is produced by at least three synergistic venom proteins. One of these proteins is identified as a phospholipase A sub(2) (EC 3.1.1.4) which exists in two isozymic forms, alpha and beta , with molecular weights of 45,000 and 43,000, respectively. The beta isozyme has been purified to homogeneity. It is a single-chained glycoprotein with an isoelectric point (pI) of 8.8 and represents 70% of the phospholipase activity of the venom. The activity of the beta isozyme is relatively labile and is inactivated by 3.5 M urea or by heating at 45 degree C. It is most stable at pH 4.0 and loses 50% of its activity at pH values below 3.5 and above 8.0. A second venom protein has also been purified. It is essential for the hemolytic activity of the venom and is termed co-lytic factor (CLF). It is a monomeric glycoprotein having a pI of 4.5. CLF has a molecular weight of approximately 98,000, a sedimentation coefficient of 4.8 S, and is prolate in shape, having a frictional ratio of about 1.6. CLF constitutes about 1.25% of the total venom protein and is assayed by reversing fatty acid inhibition of the venom hemolysis activity.

(CGC) was developed to det. pollutants in water. The extractor is connected to a transfer line through a micro T-piece after a valve, permitting transfer of thermal-desorbed components directly into GC instead of through a valve. High sample flow rate and vacuum are used during the extn. to improve the sample and solid phase contact, leading to faster equil., higher enrichment factor, and better reproducibility. Operating principles and device configuration make automation possible. 487. Guillard, K. and Kopp, K. L. (Nitrogen Fertilizer Form and Associated Nitrate Leaching From Cool-Season Lawn Turf. *J environ qual. 2004 sep-oct; 33(5):1822-7. [Journal of environmental quality]: J Environ Qual.*
Chem Codes: Chemical of Concern: PSM Rejection Code: FATE.

ABSTRACT: Various N fertilizer sources are available for lawn turf. Few field studies, however, have determined the losses of nitrate (NO(3)-N) from lawns receiving different formulations of N fertilizers. The objectives of this study were to determine the differences in NO(3)-N leaching losses among various N fertilizer sources and to ascertain when losses were most likely to occur. The field experiment was set out in a completely random design on a turf typical of the lawns in southern New England. Treatments consisted of four fertilizer sources with fast- and slow-release N formulations: (i) ammonium nitrate (AN), (ii) polymer-coated sulfur-coated urea (PCSCU), (iii) organic product, and (iv) a nonfertilized control. The experiment was conducted across three years and fertilized to supply a total of 147 kg N ha(-1) yr(-1). Percolate was collected with zero-tension lysimeters. Flow-weighted NO(3)-N concentrations were 4.6, 0.57, 0.31, and 0.18 mg L(-1) for AN, PCSCU, organic, and the control, respectively. After correcting for control losses, average annual NO(3)-N leaching losses as a percentage of N applied were 16.8% for AN, 1.7% for PCSCU, and 0.6% for organic. Results indicate that NO(3)-N leaching losses from lawn turf in southern New England occur primarily during the late fall through the early spring. To reduce the threat of NO(3)-N leaching losses, lawn turf fertilizers should be formulated with a larger percentage of slow-release N than soluble N.

488. Guillard, K., Morris, T. F., and Kopp, K. L. (1999). The Pre-Sidedress Soil Nitrate Test and Nitrate Leaching From Corn. *Journal of Environmental Quality, 28 (6) pp. 1845-1852, 1999*.
Chem Codes: Chemical of Concern: PSM Rejection Code: FATE.

ISSN: 0047-2425
Abstract: The pre-sidedress soil nitrate test (PSNT) is recommended in many states as a best management practice (BMP) for corn (Zea mays L.). A 2-yr study was conducted in Connecticut on a Woodbridge fine sandy loam soil (coarse loamy, mixed, mesic Aquic Dystrochrept) to determine NO inferior 3-N concentrations and losses in soil water from corn managed with three different N fertilization regimes: (i) PRE, 196 kg N ha superior - superior 1 applied preplant; (ii) PSNT-1, 90 kg N ha superior - superior 1 applied at preplant and any remaining N needs estimated by the PSNT (0 kg ha superior - superior 1 in 1995 and 45 kg ha superior - superior 1 in

1996); and (iii) PSNT-2, no preplant N and all N needs estimated by the PSNT (34 kg ha superior - superior 1 in 1995 and 123 kg ha superior - superior 1 in 1996). Percolate was collected with zero-tension pan lysimeters. Flow- weighted NO inferior 3-N concentrations from the PRE treatment were 22.3 mg L superior - superior 1 in 1995 and 17.4 mg L superior - superior 1 in 1996; the PSNT treatments were less than 8.0 mg L superior - superior 1. Losses of NO inferior 3-N as a percent of N applied in 1995 were 20%, 10%, and 12% for PRE, PSNT-1, and PSNT-2, respectively, and 31%, 21%, and 21%, respectively, in 1996. Greatest leaching losses occurred after corn harvest. Corn yields were not significantly (P greater than 0.05) different among N treatments. These findings suggest that a well calibrated soil N test can reduce excess fertilization and the potential for NO inferior 3 contamination of ground water.

ABSTRACT: BIOSIS COPYRIGHT: BIOL ABS. The U.S. Food and Drug Administration conducts the Total Diet Study to determine dietary intakes of selected pesticides, industrial chemicals, and elements (including radionuclides). The results reported here reflect the sampling period from June 1984 to April 1986. The study involves retail purchase of foods representative of the total diet of the U.S. population, preparation for table-ready consumption, and individual analyses of 234 items depicting the diets of 8 population groups. The diets were based on 2 nationwide food consumption surveys. The data presented represent 8 food collections (also termed "market baskets") in regional metropolitan areas during the 2-year period. Dietary intakes of over 90 analytes are presented for the 8 population groups, which range from infants to elderly adults. Intakes of selected population groups are compared with representative previous findings. As reported previously, average daily intakes are well below acceptable limits.

ABSTRACT: BIOSIS COPYRIGHT: BIOL ABS. The U.S. Food and Drug Administration conducts the Total Diet Study to determine dietary intakes of selected pesticides, industrial chemicals, and elements (including radionuclides). This paper report results for the sampling period July 1986 to April 1991. The study involves retail purchase of foods representative of the "total diet" of the U.S. population, preparation for "table-ready" consumption, and individual analyses of 234 items making up the diets of 8 population groups. The diets were based on 2 nationwide food consumption surveys. The data presented represent 21 food collections (also termed "market baskets") in regional metropolitan areas during the 5-year period. Dietary intakes of nearly 120 analytes are presented for elderly adults. Intakes of selected population groups are compared with representative findings from earlier Total Diet Study sampling periods. As reported previously, average daily intakes are well below acceptable limits.

California leads the nation in agricultural pesticide use. A mandatory reporting system for all agricultural pesticide use in the state provides information on the active ingredient, amt. used, and location. Pesticide use d. was calcd. to quantify agricultural pesticide use in California block groups for a childhood cancer study. Pesticides with similar toxicol. properties (probable and possible carcinogens, genotoxic compds., developmental or reproductive toxicants) were grouped together. To prioritize pesticides, pesticide use was weighted by the carcinogenic and exposure potential of each compd. Top ranking individual pesticides were propargite, Me bromide, and trifluralin. A geog. information system calcd. pesticide use d. in pounds/mi2 of total land area for all United States census-block groups in the state. Most block groups (77%) averaged <1 lb/mi2 of use for 1991-1994 for pesticides classified as probable human carcinogens; however, at the high end of use d. (>90th percentile), there were 493 block groups with >569 lb/mi2. Approx. 170,000 children under 15 yr of age were living in these block groups in 1990. The distribution of agricultural pesticide use and no. of potentially exposed children suggested pesticide use d. would be of value for a study of childhood cancer. ABSTRACT: PESTAB. The reentry problem pertains to illness (no confirmed fatalities to date) among agricultural workers entering a treated area following pesticide application. The problem is limited to cholinesterase-inhibiting pesticides at present. Residue levels of these pesticides on soil, fruit, and foliage are affected by formulation, method of application, humidity, rain, temperature, dust levels, and other factors. Methods of lowering residue amounts are being investigated. Washing trees with water may be a useful procedure. Studies on the physical and chemical aspects of reentry in citrus groves have been fairly thorough, but research is continuing on the role of soil types (especially clay contents) in modifying organophosphate residues. Physiologically active residues are transferred to agricultural workers primarily via dislodgable foliar residues and soil surface "dust" residues. Both parent compound (P=S) and oxon (P=O) residues are readily reduced in the presence of water. In commercial citriculture long-lived dislodgable organophosphate residues are exceptional. The role of clays in increasing longevity of available residues is so great that some groves may be considered potentially reentry hazardous based on soil type alone. A protocol is suggested for acquiring the necessary chemical, biological, and physical data for reentry evaluation.

To account for both precursor metabolic effects and primary AChE inhibition, the authors included absorption, distribution, metab., excretion (ADME) effects, ligand binding, and reactive AChE phosphorylation and aging in a detailed but computationally expedient phenomenol. toxicity model. Ligand neg. accessible surface area (NASA) was used as a generic ADME descriptor, while relevant metabolic, phosphorylation, and aging reactions were assessed via quantum chem. enthalpy calcns., and the binding affinity of the Michaelis complex was quantified via Comparative Mol. Field Anal. (CoMFA). The resulting model correlates very well (R2 = 0.90) with exptl. acute toxicity measurements and provides useful mechanistic insight into the

underlying toxicity. Model predictivity was validated by leave-one-out cross-validation (Q2 = 0.82). The Michaelis binding affinity descriptor has the largest wt. in our model, but subsequent covalent inhibition and prior ADME effects also exhibit significant effects. 495. Guo, M. (Groundwater Quality Under the Influence of Spent Mushroom Substrate Weathering. *J environ monit. 2005, oct; 7(10):1007-12. [Journal of environmental monitoring : jem]: J Environ Monit.*
Chem Codes: Chemical of Concern: PSM Rejection Code: FATE.

ABSTRACT: Nitrate and other solutes resulting from field-weathering of spent mushroom substrate (SMS) percolate into underlying soils and may migrate to groundwater. A field trial was conducted to investigate the potential influences of SMS weathering on groundwater quality. Spent mushroom substrate was deposited at 90 and 150 cm pile depths over a Typic Hapludult and weathered for 2 years. Eight casing wells were installed around the SMS piles to monitor the quality changes of groundwater with a high seasonal water table of 760 cm below the surface. Although leachate solutes had moved more than 200 cm deep in soil from the surface, no significant changes of groundwater quality caused by SMS weathering were observed even one year after removal of the SMS piles (3 years total). The groundwater had pH, electrical conductivity (EC) and dissolved organic carbon (DOC) of 4.3-5.7, 0.2-0.3 dS m(-1) and 0.7-2.2 mg L(-1), respectively. The major inorganic ions were Mg(2+), Ca(2+), Na(+), Cl(-), SO(4)(2-) and NO(3)(-), with a concentration range of 2.5-68.3 mg L(-1). The results suggest that SMS leachate solutes migrated fairly slow in deep subsurface soils of the experimental field. Considering that leachate solutes may move several meters in soil through preferential flow channels, weathering of SMS in fields with a high seasonal groundwater table >or=5 m below the ground is recommended. Conservatively, SMS weathering should be conducted on compact surfaces and leachate be collected and reused as liquid fertilizers.

ABSTRACT: Field weathering of spent mushroom substrate (SMS) produces soluble compost leachate that percolates into underlying soils and may adversely impact groundwater. Laboratory experiments were conducted to investigate movement and retention of SMS leachate solutes in subsurface soil columns. Spent mushroom substrate leachate with high concentrations of dissolved organic matter (DOM) and inorganic salts was passively loaded to intact and repacked columns of Bt1 soil (fine-loamy, mixed, semiactive, mesic Typic Hapludults) and effluents were monitored for changes in chemical composition. Transport of SMS leachate in undisturbed soil cores was mainly via preferential flow, whereas matrix flow was predominant in repacked soil columns. Leachate DOM and phosphate were sorbed by soil minerals while Cl-, SO4(2-), Na+ and NH4+ were eluted. Leachate K+ displaced exchangeable native cations and was retained. Biodegradation of leachate DOM resulted in reduction and elution of soil Mn and Fe, especially in repacked

columns. Persistent anoxia also inhibited nitrification. Precipitation of gypsum and CaCO3 blocked preferential flow channels, and movement of SMS leachate was subsequently reduced. The results demonstrate that SMS leachate migrates via rapid preferential flow initially, followed by matrix flow at a lower rate. Leachate solutes may transport to depth in soil profiles through preferential channels. To protect water resources, weathering of deep SMS piles should be conducted on compact surfaces or in fields with a condensed soil layer (no structural cracks) above the groundwater table, and measures controlling leachate runoff be imposed.

ABSTRACT: Passive leaching by rainfall and snowmelt is a popular method to treat piles of spent mushroom substrate (SMS) before its reuse. During this field weathering process, leachate percolates into the underlying soils. A field study was conducted to examine the chemistry of SMS leachate and effects of infiltration. Two SMS piles were deposited (90 and 150 cm in height) over a Typic Hapludult and weathered for 24 mo. Leachate was collected biweekly using passive capillary samplers. The SMS leachate contained high concentrations of dissolved organic carbon (DOC; 0.8-11.0 g L(-1)), dissolved organic nitrogen (DON; 0.1-2 g L(-1)), and inorganic salts. The pH, electrical conductivity, and acid neutralizing capacity were 6.6 to 9.0, 21 to 66 ds m(-1), and 10 to 75 mmolc L(-1), respectively. Inorganic chemistry of the leachate was dominated by K+, Cl-, and SO24-. Leachate DOC was predominantly low molecular weight (< 1000 Da) organic acids. During 2 yr of weathering, the 90-cm SMS pile released (per cubic meter of SMS) 3.0 kg of DOC, 1.6 kg of dissolved N, and 26.6 kg of inorganic salts. The 150-cm pile released (per cubic meter of SMS) 2.8 kg of DOC, 0.7 kg of dissolved N, and 13.6 kg of inorganic salts. The 150 cm pile retained more water and exhibited lower net nitrification compared with the 90-cm pile. The top 90 cm of soil retained 20 to 89% of the leachate solutes. Weathering of SMS in piles of 90 cm depth or greater may adversely affect ground water quality.

ABSTRACT: BIOSIS COPYRIGHT: BIOL ABS. The water balance method is a widespread approach for estimating the volumes of leachate that a landfill is likely to produce. Yet, this method does not always adequately reproduce observed patterns of landfill leachate production. This paper proposes a modified approach that tries to account for the hydrologic behaviour of the waste in a manner which is believed to be consistent with field measurements. The conceptual model considers that a certain proportion of infiltration into the waste percolates rapidly through preferential pathways, while the remaining infiltration is absorbed by the waste and released following a first-order kinetic relationship. A comparison between the proposed model and leachate volumes measured daily at two municipal solid waste landfills in France over a period of up to nine months suggests that the proposed approach is capable of reproducing observed behaviour. Moreover, the values attributed to the fitting parameters in order to obtain a

Ab - biosis copyright: biol abs. The susceptibility of two populations of the citrus leafminer, phyllocnistis citrella, collected from matsubase in kumamoto prefecture and naruto in tokushima prefecture, to several insecticides was determined by field tests and laboratory bioassay. Citrus leaves infested with 1st and 2nd instar larvae were dipped into insecticide solutions and kept in petri dishs containing wet filter paper at 25ę c. The mortalities were determined 48 h. The matsubasc population was resistant to fenvalerate (lc50 = 30.1 Ppm) and permethrin (lc50 = 5.27 Ppm), but the naruto population was susceptible. The susceptibility to phosmet was low in the matsubase (lc50 = 3,212 ppm) and naruto populations (lc50 = 150 ppm). These results are consistent with the trend found in field tests with insecticides to control p. Citrella.

501. Ha, S. R., Dung, P. A., and Lee, B. H. (Impacts of Agrochemical Fertilizer on the Aquatic Environment of Paddy Fields in Vietnam. *Water sci technol. 2001; 43(5):193-202. [Water science and technology : a journal of the international association on water pollution research]: Water Sci Technol.*
Chem Codes: Chemical of Concern: PSM Rejection Code: SURVEY.

ABSTRACT: To evaluate the impacts of agrochemical fertilizer application on the aquatic environment of paddy fields in tropical regions, 7.04 ha of paddy field situated in northern Vietnam were selected as a study area. The fate of nutrient constituents was surveyed through a questionnaire as well as analytical observation. Taking the major environmental components of the paddy field into account, a mass-balance flow regarding fertilizing constituents such as nitrogen and phosphate was built up and used to estimate the contribution of fertilizer to paddy field water pollution. In the mass-flow analysis, the randomness of fertilizer used by local farmers is incorporated within the conventional input-output model. For the control volume of soil in 0-40 cm below paddy plot surface, the estimated average concentrations in soil were 1.8 ppm for inorganic nitrogen and 1.3 ppm for inorganic phosphate on the assumption of 50% non-excessive probability. From the reasonable consistency of the deduced concentrations of nutrients with observed ones, not only the mass balance of fertilizing substances but also the impacts of fertilizer on the paddy field aquatic environment in Vietnam could be understood. On the results from

nutrient mass-balance analysis, it was found that 11.3-13.3 kg N/ha would percolate into the underground aquifer that is linked to surface channel flow in the vicinity of the paddy plots and affect the irrigation water quality. The nutrient portion in the materials harvested as grain and straw occupied 58% of total dosed nitrogen and 75.6% of total supplied phosphorous.

Conventional every-row spraying was used in almost every orchard during the 2-yr period. Phosmet [732-11-6] and azinphosmethyl [86-50-0] were the predominant insecticides utilized, whereas captan [133-06-2], Dikar [8064-42-4], and benomyl [17804-35-2] were the most frequently used fungicides. Superior oil applied in early spring and cyhexatin [13121-70-5] were the most common materials for control of mites. Insecticides and fungicides were applied at nearly half the Ohio recommended full dil. rates. Av. expenditures for insecticides in 1979 were $107/ha and $115/ha in 1980. Losses from principal insect pests, redbanded leafroller (Argyrotaenia velutinana), and plum curculio (Conotrachelus nenuphar), were <2% annually. [on SciFinder (R)] 0022-0493

504. Hall, J. K. , Mumma, R. O., and Watts, D. W. (1991). Leaching and runoff losses of herbicides in a tilled and untilled field. *Agriculture, Ecosystems & Environment* 37: 303-314.
Chem Codes: Chemical of Concern: PSM Rejection Code: FATE.

Transport of herbicide mass by leaching and runoff was evaluated over several years. Herbicides were applied at recommended rates to conventional tillage (CT) and no-tillage (NT) planted corn (Zea mays L.) fields on Hagerstown silty clay loam (Typic Hapludalf). Pre-emergence herbicide treatments on each tillage system included simazine (6-chloro-N,N'-diethyl-1, 3,5-triazine-2,4-diamine), atrazine (6-chloro-N-ethyl-N'-(1-methylethyl)-1,3,5-triazine-2,4-diamine), cyanazine (2-[[4-chloro-6-(ethylamino)-1,3,5-triazin-2-yl]amino]-2-methylpropanenitrile) and metolachor (2-chloro-N-(2-ethyl-6-methylphenyl)-N-(2-methoxy-1-methylethyl) acetamide). Application rates (active ingredient basis) were 1.7 kg ha-1 (simazine, atrazine) and 2.2 kg ha-1 (cyanazine, metolachlor). Percent herbicide losses (1984-1988) in root zone leachates, sampled in pan lysimeters embedded 122 cm deep in the soil profile, were greater under NT than under CT corn production. The opposite was true for runoff losses of herbicides and the magnitude of loss was less for runoff than for leaching. Total percolate yield and spray date-leaching or runoff event intervals were critical factors controlling surface or subsurface herbicide "loadings" in water. Areal losses were directly related to percolate or runoff yield and inversely related to these time increments. Also, unusually dry conditions in 1988 increased the soil residence time for cyanazine, resulting in a late-season leaching pattern somewhat atypical for this low persistence herbicide. During the 5 years, average CT leaching losses calculated from herbicide concentrations and lysimeter percolate volumes, collected in several pits, ranged from less than 0.01 to 1.05% of sprayed amounts. The more persistent herbicides, atrazine and simazine, were generally at the upper level of this range. Under NT conditions, average leaching losses ranged from 0.05 to 6.16% of sprayed amounts. Cyanazine losses were equal to or greater than simazine and atrazine losses in several seasons. In general, metolachor was the least mobile herbicide. Runoff losses (3-5% slope) were greatest in 1985 and 1986 for simazine under CT (0.62 and 0.51% of the applied rate, respectively). Respective losses under NT were 0.18% and less than 0.01%.

experiment. *Journal of Aerosol Science* 24: 211-226.
Chem Codes: Chemical of Concern: PSM Rejection Code: MODELING.

Models for the unipolar charging of fibers were developed. The theoretical models using idealized geometries--either prolate spheroids or cylinders--and considering both the free-molecular and continuum cases served as a basis for numerical simulations. Simulation results showed that the fibers can carry more charges than equal surface area spheres. In the experimental component of this study, a prototype charger was designed and constructed. The rate of charging was measured as a function of fiber length and charger parameters. It was found that the fiber collection efficiency depends both on charge numbers and the aerodynamic drag of the fiber. The fiber length classification can be achieved by electrostatic precipitation.

Abstract: Californiagrass (paragrass) irrigated with effluent from secondarily treated domestic sewage showed excellent response as a means for disposal of large amounts of water, effective removal of nitrogen, and high production of excellent fodder. This grass, already well established in Hawaii, is used for pasture and fodder, endures flooding, and because of its allelopathic habit forms dense, easily maintained monostands. The water, nitrogen, and biomass budgets of the grass over a 17-mo period, from April 1979 through August 1980, were measured in eight large percolate-style lysimeters filled with the Lahaian series soil (Tropeptic Haplustox).

Chem Codes: Chemical of Concern: PSM Rejection Code: HUMAN HEALTH.

ABSTRACT: BIOSIS COPYRIGHT: BIOL ABS. There is concern that orange juice from foreign countries may contain residues of pesticides not allowed in the United States. Of 17 orange juices examined, 15 listed Brazil as the source of all or part of the juice used. Six samples contained residues. All pesticides found were allowed for use in the United States, and all residues were well below EPA allowable tolerances in oranges.

508. Hansen, Hans Christian Bruun, Bergen Jensen, Marina, and Magid, Jakob (1999). Phosphate sorption to matrix and fracture wall materials in a Glossaqualf. *Geoderma* 90: 243-261.
Chem Codes: Chemical of Concern: PSM Rejection Code: CHEM METHODS.

Phosphate retaining properties of macropore wall materials may influence the extent of phosphate leaching via preferential flow. Phosphate sorption to soil matrix material has been compared with sorption to fracture wall materials consisting of inner iron-oxide depleted albic coatings rimmed by reddish iron-oxide enriched quasicoatings. The latter contains 15 times as much Fe oxide, 2 times as much Al (hydr)oxide and 5-6 times as much total P than the albic material, which represent the most P-depleted material in the profile. Oxalate extractable P (Po) amounts to of the total P contents of the samples. Smectite predominates in the fracture walls and acid subsoils, but has partly transformed into hydroxy-interlayered smectite (HIS) in the upper limed soil horizons. Langmuir parameters derived from phosphate sorption isotherms show no correlation for sorption to whole soil samples and the corresponding clay fractions. The phosphate sorption capacity at a threshold equilibrium concentration of 10 [mu]M (Padst (10 [mu]M)) is measured as the content of Po plus the amount of phosphate sorbed during 7 days, and can be related to Alo+Feo: Padst (10 [mu]M)=(0.0404+/-0.0046)[middle dot](Alo+Feo)***+3.569. The Padst (10 [mu]M) values vary between 4 and 14 mmol P kg-1, lowest in the albic fracture walls and highest in the iron enriched quasi-coatings. The sorption capacity of the metal oxide free clay does not appear to correlate with smectite or HIS contents. In total, the clay fraction contributes with about 50% of the whole soil sorption capacity in agreement with 40-60% of the total soil Alo+Feo being present in the clay fraction. At a solution phosphate concentration of 10 [mu]M, the Ap horizon is found to be almost phosphate saturated whereas subsoil horizons including the fractures have phosphate saturations <=50% and, hence, can strongly sorb P. The low phosphate saturation of fracture walls indicates that they do not act as major sinks of phosphate-rich solutions from topsoil horizons, either due to kinetic constraints, or due to a flow pattern not allowing P-rich solution to percolate fractures. phosphate sorption/ macropores/ iron oxides/ pseudogley/ HIS/ smectite/ phosphate sorption capacity http://www.sciencedirect.com/science/article/B6V67-3WWRF2R-H/2/6d10fec2d41a1da8ecdb361dc4a4e7b4

Chem Codes: Chemical of Concern: PSM Rejection Code: FATE.

ISSN: 0190-4167
Abstract: The long-term effects of using alkaline water on the chemical properties of sand soils were simulated by treating 36 cm tall, 5 cm diameter columns of soil with water amounts equivalent to that typically applied to cranberries (Vaccinium macrocarpon Ait.) during one year (152 cm, 3 liters), two years (304 cm, 6 liters), or three years (456 cm, 9 liters). Columns received either alkaline pond water [148 mg L superior - superior 1 calcium carbonate (CaCO inferior 3) equivalent, pH 8.0], pond water acidified with sulfuric acid (H inferior 2SO inferior 4) to pH 5.0,

or no water. Water was applied to the top of the soil in 15.2 cm increments and allowed to percolate slowly through and out the bottom of the column. The same treatments were applied to an acidic soil (pH 5.6) and a neutral soil (pH 7.1). The equivalent of three years of alkaline water use raised the pH of the acidic soil to 7.5, and that of the neutral soil to pH 7.8. Acidified water did not change the pH of the acidic soil, but decreased that of the neutral soil to 6.2. Use of alkaline water increased calcium (Ca) levels from 250 mg kg superior - superior 1 to 738 mg kg superior - superior 1 in the acidic soil. Soil Ca levels were not affected by acidified water in either soil. Treatments had inconsistent effects on potassium (K) and magnesium (Mg) levels in the soils. Based on these results, high alkalinity water that has been acidified prior to use would not adversely affect the pH or Ca levels in cranberry soils over a three-year period.

510. Harding, Stephen E., Day, Kathryn, Dhami, Rajesh, and Lowe, Philip M. (1997). Further observations on the size, shape and hydration of kappa-carrageenan in dilute solution. *Carbohydrate Polymers* 32: 81-87.
Chem Codes: Chemical of Concern: PSM Rejection Code: CHEM METHODS.

This study builds on previous studies of the important commercial polysaccharide kappa ([kappa])-carrageenan by confirming, using quite different methdology, the molecular weight and the asymmetric conformation of the [kappa]-carrageenan molecule and also provides an estimate of its large capacity to imbibe water. Studies (sedimentation velocity and equilibrium analytical ultracentrifugation and viscometry) were performed on unfractionated material in a dilute solution based on a sodium phosphate/chloride buffer (pH 6.5, I = 0.10). Low-speed sedimentation equilibrium using Rayleigh interference optics and using three different methods of extrapolation procedure yields a concensus weight average molecular weight, Mw, of (300 000 +/- 40 000) g/mol; this (i) demonstrates the relation between `whole cell average' and `point weight average' molecular weight approaches and (ii) is consistent with other published values based on light scattering procedures. A single non-ideality virial coefficient was shown to be insufficient to explain the concentration dependence behaviour of the apparent weight average molecular weight, Mw,app. Sedimentation velocity yields a sedimentation coefficient, s20,w of (4.19 +/- 0.20) S and a sedimentation concentration regression coefficient, ks of (591 +/- 40) ml/g; low-shear viscometry yielded an intrinsic viscosity [[eta]]of (630 +/- 60)ml/g and a Huggins constant K[eta] of ~0.36. From these data, the hydration independent Wales/van Holde ratio (ks/[[eta]]) of ~0.9 is consistent with an extended conformation and making the crude approximation of a rigid structure, corresponds to an equivalent hydrodynamic prolate ellipsoid of aspect ratio ~15:1. These data also yield a frictional ratio f/fo of ~7.6 which is consistent with a large hydration (~50 g water per g of dry polysaccharide, corresponding to a molecular expansion of ~100x), consistent with one of [kappa]-carrageenans key functional properties in foods as a high water binder. No further comment is made about the order-disorder transition claimed for these molecules.

Fungicides were the only class of pesticides that affected cumulative no. of T. urticae-days per leaf in tree canopies and colonization success - the ratio of T. urticae-days to no. of immigrating T. urticae caught in sticky bands on tree trunks. In 2000, increased nos. of T. urticae-days in the tree canopy were assocd. with more frequent applications of ethylene bis-dithiocarbamate (EBDC) fungicides and with higher fungicide toxicity scores, which indicate cumulative level of suppression of the phytoseiid predator Typhlodromus pyri by all fungicide applications. Higher rates of colonization success were also assocd. with higher toxicity scores. EBDC's applied in 2000 promoted T. urticae immigration as indicated by their counts on sticky bands. In 2000 and 2001, no. of T. pyri-days in the tree canopies was decreased by more frequent EBDC applications and by higher fungicide toxicity scores. Promotion of T. urticae in tree canopies by EBDC's was attributed to their toxicity to T. pyri. Both T. pyri and another phytoseiid, Amblyseius fallacis, were found in ground cover vegetation. Hence, increased immigration from the ground cover attributed to the toxicity of EBDC's to T. pyri and, esp., to A. fallacis, which is a specialist predator of spider mites and an effective natural enemy of T. urticae. <u>Chem Codes</u>: Chemical of Concern: PSM <u>Rejection Code</u>: SURVEY.

ABSTRACT: BIOSIS COPYRIGHT: BIOL ABS. Northern leopard frogs (Rana pipiens) and green frogs (Rana clamitans) were evaluated at eight wetland sites, four of which were within apple orchards, to determine if environmental changes associated with orchard management affected measured biological parameters. Size, age, genetic variation, condition indices, levels of circulating steroid hormones, 7-ethoxyresorufin-O-deethylase activity (EROD), and organochlorine and organophosphorus residues in breeding males sampled at pond sites in orchards were compared to the same parameters measured in breeding males from reference sites. Also, the size and physiological condition of young-of-the-year captured in orchard and reference ponds were compared. No evidence of a reduction in genetic variation was found in populations of either species at any sites, but unexpectedly high average heterozygosity values (0.191-0.282) in concert with low overall fixation indices (0.012-0.059) in adults of both species did suggest that po

ABSTRACT: TD3: Commercial development of oil shale resources will produce vast quantities of

processed shale waste. The presence of potentially toxic trace elements, inorganic salts, and potentially toxic residual organic constitutents make the disposal of vast quantities of processed shale a potential environmental problem. To be environmentally acceptable, processed shale disposal must: result in a physically stable structure, prevent or minimize release of potentially toxic compounds, and provide an economically acceptable post-land use. Water is the common element underlying all factors important to the environmental stability of disposed solid waste. The leaching and transport of solubles by water in processed shale embankments may result in degradation of local surface and groundwater quality. The major purpose of this research is to physically model, study, and describe the redistribution and movement of water and percolates in lifts of disposed processed oil shale under simulated natural environmental

Abstract: Overland flow, on slopes of 5 and 11%, was used as a means of treating wastewater effluent from the second cell of a swine waste anaerobic lagoon system. Wastewater samples from both surface runoff and soil percolate (depths of 0.3, 0.9, and 1.5 m) were collected and analyzed for TKN-N, NH sub(4)-N, ON-N, NO sub(3)-N, pH, COD, K, EC, and TP-P. Using these data, along with the hydraulic loading rates and quantitative runoff collection, mass balances on the above parameters were calculated to determine the surface treatment of the lagoon effluent. These mass balances suggest that overland flow is an excellent treatment system for liquid lagoon effluents with mass reductions of greater than 60% for all parameters on both slopes, except NO sub(3)-N, which had an approximate increase of 1.7 times on the 11% slope. Samples collected from the three lysimeter depths (soil percolate) suggest that NO sub(3)-N leaching from the plots may be a concern over an extended period of use. The runoff from overland flow systems of this

type will require further treatment.

Chem Codes: Chemical of Concern: PSM Rejection Code: FATE.

ABSTRACT: BIOSIS COPYRIGHT: BIOL ABS. Ion concentrations in snowmelt runoff, forest-floor percolate and mineral-soil percolate collected in a tolerant hardwood forest at the Turkey Lakes Watershed, ON, were determined during the spring snowmelt of 1986. The results were examined to assess the modification of snowmelt water after contact with the forest soil. Concentrations of NO3- increased from 17 to 201 mumolc L-1 and SO42- increased from 25 to 107 mumolc L-1 as meltwater passed through the organic layers and the upper mineral-soil horizons. Mineralization of organic N and S, and desorption of SO42+ from the soil, provide sources of these ions for leaching during the snowmelt period. Iron-exchange reactions in the forest floor and upper mineral soil resulted in a decrease in H+ and an increase in Ca2+ concentrations in solution. In the steep topography of this forested basin, the altered snowmelt solutions are rapidly transported downslope towards the aquatic system by lateral flow. Processes within the fo

Abstract: Ion concentrations in water collected within a forest of sugar maple and yellow birch at the Turkey Lakes Watershed near Sault Ste. Marie, Ontario were examined from 1982 to 1984 to determine sources of acidity and the extent of cation leaching from forest-floor horizons. Volume-weighted concentrations and ion fluxes in throughfall and forest-floor percolate during the growing and dormant seasons were calculated. Hydrogen ion content of the forest-floor percolate decreased in relation to that of throughfall in the dormant season and increased in the growing season. Hydrogen ion deposition in throughfall could account for 100% of the flux of H super(+) through the forest floor in the dormant period, and 40% of the flux during the growing season. Sources of NO sub(3) super(-) and organic anions within the ecosystem and major external inputs of NO sub(3) super(-) and SO sub(4) super(2-) were critical factors that influenced cation mobility in the forest floor.

523. Heck, Henry d'A. (1974). Characterization of the threonine-sensitive aspartokinase-homoserine dehydrogenase of Escherichia coli K12 by transient electric birefringence. *Archives of Biochemistry and Biophysics* 160: 205-214.
Chem Codes: Chemical of Concern: PSM Rejection Code: BACTERIA.

The rotatory diffusion constant of aspartokinase I-homoserine dehydrogenase I of Escherichia coli K12 was determined by the method of transient electric birefringence. Its value extrapolated to zero concentration in water at 20[degree sign]C is 2.98+/-0.09x105 sec-1. Combination of this result with the known translational hydrodynamic properties of the protein permits the calculation of two equivalent ellipsoids of revolution: prolate, axial ratio, 2.5+/-0.4, and effective volume, 1.17+/-0.08x106 A3; and oblate, axial ratio, 0.05+/-0.045, and effective volume, 0.26+/-0.24x106 A3. The probable structure and symmetry of this tetrameric allosteric protein is discussed in regard to these data and to other available information. Other properties of the ellipsoidal models are predicted, including the hydrodynamic radii of gyration, excluded volumes, limiting viscosity number, and harmonic mean relaxation times. The second virial coefficient is calculated, assuming that it arises entirely from excluded volume effects. The result obtained is in excellent agreement with experimental values determined in moderate salt solutions near neutral pH.

524. Herbert, Thomas J. (1983). On the relationship between interception of direct solar radiation by cactus bodies and plant leaves. *Journal of Theoretical Biology* 105: 619-629.
Chem Codes: Chemical of Concern: PSM Rejection Code: MODELING.

The interception of direct solar radiation by cactus bodies is calculated by computation of the

average of the cosine of the angle of incidence over the surface of two models: a cylindrical model with a horizontal top and a prolate or oblate ellipsoidal model. An expression is obtained for the fraction of maximum possible solar radiation intercepted by a particular surface element for fixed values of the zenith angle of the sun. This expression is averaged by numerical integration over the surface of the cactus body to yield the average cosine of angle of incidence. The resulting relationships between cosine of angle of incidence and solar zenith angle show significant differences with respect to similar relationships for flat leaves. However, if a correction is applied for attenuation of direct solar radiation by the atmosphere, differences are greatly reduced.

To measure the history of net SOC accumulation there, we analyzed the upper 40 m of an ice core from Austfonna, the largest ice cap in Eurasia, for several legacy organochlorine (OC) compds. and current-use pesticides (CUPs) including organophosphorus (OP), triazine, dinitroaniline, and chloroacetamide compds. Five OP compds. (chlorpyrifos, terbufos, diazinon, methyl parathion, and fenitrothion), two OCs (methoxychlor and dieldrin), and metolachlor-an herbicide-had historical profiles in the core. The highest OC concn. obsd. was aldrin (69.0 ng L-1) in the surface sample (1992-1998). The most concd. OP was dimethoate (87.0 ng L-1) between 1986 and 1992. The surface sample also had highest concns. of pendimethalin (herbicide, 18.6 ng L-1) and flutriafol, the lone obsd. fungicide (9.6 ng L-1). The apparent atm. persistence of CUPs likely results from little or no oxidn. by OH.bul. during the dark polar winter and in spring. Long-range atm. pesticide transport to Svalbard from Eurasia is influenced by the pos. state of the North Atlantic Oscillation Index since 1980 and also by occasional fast-moving summer air masses from northern Eurasian croplands. Citations: Sancho, J; J Chromatogr 1997, 761, 322 The simplification of sample prepn. in the field of pesticide residue anal. (PRA) is receiving increasing attention in the last years, as sample handling steps are highly time-consuming and the source of important anal. errors. Besides, they generate the bulk of chem. residues (mainly org. solvents). Many papers have pointed out the need for developing new extn. methods in order to simplify extn. procedures and to reduce in scale (microextn. procedures) thus reducing solvent and reagents consumption. Two research lines can be pointed out in the field of PRA by Gas Chromatog.: the use of Solid Phase Microextn. (SPME) and the application of procedures based on large vol. injection (LVI). As regards LVI, our studies have been devoted to the optimization of the injection technique itself (introducing >100-200 mL in the GC through the use of a modified on-column injection port or using a PTV injection port) and subsequently to the application of microextn. procedures (LLME and SPE) that use only reduced amt. of sample and org. solvents. We have applied these procedures to the detn. of several OP's and triazines in groundwater and surface water. One of the main advantages is their great sensitivity (LOD's in the range of few ppt) using sample vols. of only 5-50 mL. The development of LVI is the preliminary step for LC-GC coupling, which could allow the complete automation of sample prepn. Our 2nd research line in GC anal. has been directed towards the optimization and application of SPME, a technique that eliminates the need for using org. solvents in extn. processes. This technique has been applied to the detn. of several OP's and to a heterogeneous group of herbicides (including triazines, molinate and bromacil). Several advantages can be pointed out: no solvents are used for extn., all the sample extd. is introduced into the GC system, it is fast and east-to-apply, and low cost. At present, our group is studying the feasibility of applying this technique to the detn. of herbicides (and other compds.) in soil samples. As expected, LC is the best choice for the trace-level detn. of these analyses. The necessity for very sensitive and selective anal. methods has propitiated the development of multidimensional LC, distinguishing between coupling 2 high-resoln. columns (LC-LC) and solid-phase extn. coupled online to LC (SPE-LC). Compds. studied are phenylureas, triazines, phenylcarbamates, glufosinate, glyphosate and some of their metabolites. study) (detn. of, in groundwater, by liq.-liq. extn. and capillary gas chromatog. with dual detection); 7732-18-5 (Water) Role: ANST (Analytical study) (pesticide detn. in ground, by liq.-liq. extn. and capillary gas chromatog. with dual detection system) A simple multi-residue procedure has been developed and applied to the detn. of pesticides in groundwater samples from the Comunidad Valenciana, a predominantly agricultural area on the Mediterranean coast of Spain. The procedure includes liq.-liq. extn., after addn. of NaCl to the samples, and subsequent anal. by capillary gas chromatog. using a dual detection system with electron capture and nitrogen-phosphorus detectors. This method allows the detn. of >30 compds. (organophosphorus, organochlorine, and pyrethroid pesticides) at low ppb (mg/L) levels. Detection limits obtained varied between 0.01 mg/L (lindane, fonofos) and 0.5 mg/L (cypermethrin). An addnl. injection of the sample exts. into a gas chromatograph equipped with a column of different polarity and electron capture detector is used for the confirmation of chromatog. peaks. The recommended procedure has been applied to 66 groundwater samples. Pesticides, including organophosphorus and organochlorine compds., were detected in 31 of them, at levels of 0.02-0.7 mg/L. ABSTRACT: BIOSIS COPYRIGHT: BIOL ABS. A simple method for determination of 5 organophosphorus pesticides (dimethoate, chlorfenvinphos, chlorpyrifos, methidathion, and phosmet) in molluscs (Mytilus gailoprovincialis and Venus gallina) was developed, with special attention to cleanup. Organophosphorus pesticides were extracted with acetonitrile-acetone (90 + 10, v/v) in a high-speed blender. Two cleanup procedures were used to defat extracts prior to injection into a gas chromatograph: liquid-liquid partition with acetonitrile-hexane and adsorption column chromatography with silica gel. The latter was more efficient for elimination of fat and fractionation of pesticides with different polarities. Limits of detection of the overall procedure including extraction and cleanup ranged from 0.2 to 1 ng/g. Quantitative recoveries for pesticide concentrations ranging from 1 to 10 000 ng/g were obtained.

(LC) have been developed for the sample clean-up of phytoplankton, crustaceans and fish exts. prior to gas chromatog. anal. of organophosphorus pesticide residues (phorate, dimethoate, fonofos, fenitrothion, malathion, chlorpyrifos, chlorfenvinphos, methidathion and phosmet). Extn. was carried out by high-speed blending with acetonitrile-acetone (90:10, vol./vol.). The ext. was concd. by a Kuderna-Danish evapn. system and evapd. to

dryness under a gentle stream of nitrogen at 40 Deg and the residue was dissolved in n-hexane. A 1 mL portion of the hexane ext. was injected on the LC system using a silica-gel column and diode array detection for the online monitoring of lipid elution. Difference in behavior of lipids present in marine organism exts. and the wide polarity range of pesticides studied made necessary the design of specific elution procedures for each species in order to obtain pesticides in fat-free fractions using different mixts. of hexane-Et acetate as mobile phases. The automated sample clean-up procedures developed allowed the direct injection of 1 mL LC fractions contg. pesticides in the gas chromatog. (GC) system. Recoveries of pesticides in spiked samples after application of the overall procedure, including extn. of samples, LC automated clean-up and GC anal., ranged from 80 to 114% (except for phorate, 68%) and limits of detection were between 2 and 10 ng g-1, using as little as 1 g of sample per anal. The procedures developed offer several advantages: they are very efficient for fat elimination, the solvent consumption is low, and they allow fully automated clean-up. They were applied in bioaccumulation studies performed on molluscs, crustaceans and fish, and also to natural samples collected from different pollution vulnerable areas at the Mediterranean Spanish coast. Organophosphorus pesticides contg. the phosphorothioate group, azinphos-Me, chlorpyrifos, dichlorofenthion, dimethoate, parathion, phosmet, and terbufos were oxidized by chloroperoxidase in the presence of hydrogen peroxide and chloride ions. The products were identified as oxon derivs. (phosphates), where the sulfur atom from the thioate group is substituted by an oxygen atom. No hydrolysis products were detected after enzymic oxidn. of these pesticides, and no halogenation of substrates was detected. Chloroperoxidase oxidn. of relatively toxic organophosphorus pesticides produces metabolites similar to those formed by cytochrome P 450 during the metabolic activation of pesticides in vivo. However, the major difference between these biocatalysts is that further cleavage of oxons, which is typical of the P 450-catalyzed reaction, was not obsd. with chloroperoxidase. The inactivation abilities against cholinesterase from 4 different biol. origins were measured. General rules to detect and discriminate insecticides were derived from the biomol. rate consts., ki, of 55 relevant organophosphorus compds., carbamates, and carbamate metabolites. Thionophosphates were converted into more powerful inhibiting oxones by oxidn. with N-bromosuccinimide. The inactivation values, ki, differ in some cases up to 6 orders of magnitude for different insecticides,

and 3 orders of magnitude for different enzymes. The inactivation of acetylcholinesterase by organophosphorus compds. can be suppressed by reactivation with obidoxime. An acceleration of inactivation of butyrylcholinesterase by carbofuran and certain other carbamates was obsd. under the influence of bispyridinium oximes. Gradient elution was used in conjunction with pos. mode electrospray ionization tandem mass spectrometry to detect up to 171 pesticides and/or metabolites in different crop matrixes using a single chromatog. run. Pesticide residues were extd./partitioned from the samples with acetone/dichloromethane/light petroleum. The anal. performance was demonstrated by the anal. of exts. from lettuce, orange, apple, cabbage, grape and wheat flour, spiked at 3 concn. levels ranging from 0.01 to 0.10 mg/kg for each pesticide and/or metabolite. In general, recoveries ranging from 70 to 110%, with relative std. deviations better than 15%, were obtained. The recovery and repeatability data are in good accordance with EU guidelines for pesticide residue anal. The limit of quantification for all targeted pesticides and metabolites tested was 0.01 mg/kg. The selectivity and robustness of the LC-MS/MS method was demonstrated by a 1-yr comparison of its anal. results with those obtained from validated GC and LC multi-residue methods applied to more than 3500 routine samples. The validated LC-MS/MS method was implemented in the anal. scheme since 2004, replacing 4 of the conventional detection methods, i.e. GC-flame-photometric detection (acephate, methamidophos, etc.), GC-nitrogen-phosphorus detection, LC-UV detection (carbendazim, thiabendazole, imazalil and prochloraz) and LC-fluorescence detection (N-methylcarbamate pesticides). During a 3-yr period, the LC-MS/MS method was applied to the analyses of more than 12,000 samples. [on SciFinder (R)] 0021-9673 pesticide/ food/ analysis/ extn/ LC/ ESI/ MSMS

Citations: Hill, A; Food Additives and Contaminants 2000, 17, 539 Pesticide residue levels (36 pesticides and some of their metabolites) were detd. in the individual units taken from large samples of apples, bananas, celery, kiwi fruit, oranges, peaches and nectarines, pears, plums, potatoes, and tomatoes. The 65 large samples (generally about 100-110 units, but only 45 units of celery) were purchased at retail or wholesale outlets in the UK. The lots from which the samples were drawn originated from 17 different countries. Av. concns. in the samples were in the approx. range 0.002-2 mg kg-1. Unit-to-unit variability factors (97.5th percentile mg kg-1/av. mg kg-1), for the pesticide/product combination data sets in which > 10% of samples contained measurable residues (n = 106), were in the range 1.4-9.6 (11.1 based on a value of zero for data below reporting limits). Anal. variance contributed only a small proportion (up to 11%) to the overall variance of the 106 data sets. There was no evidence of a relationship between the variability factor and the commodity, country of origin, residue concn. or the physicochem. characteristics of the pesticide. The extent of variability appears to be detd. at or about the time of pesticide application. Taking non-detectable residues as half the reporting limits, the frequency distribution of variability factors was approx. log-normal, with a geometric mean of 3.4. The corresponding 95% probability limits of the variability factors were calcd. to be 1.6 and 7.6. [on SciFinder (R)] 0265-203X fruit/ vegetable/ pesticide/ contamination/ variation

A total of 130 compds. were tested. Toxicities are expressed as LC50 (median lethal dietary concns.) and are based on 5 days of dietary exposure to the test compd. followed by 3 days of untreated feed. From these data statistical comparisons between toxicities are possible for a given species. The more toxic compds. were halogen derivs. of alicyclic hydrocarbons, derivs. of phosphoric and thiophosphoric acids, and organomercurials. Carbamates, often of extreme acute toxicity to rats, were only moderately toxic to birds. Most carboxylates, ketones, organonitrogen compds., organosulfates and ureas possessed a relatively low order of toxicity. The most frequent order of species susceptibility was bobwhite >Japanese quail >ring-necked pheasant >mallard. This order correlated with their body sizes at the ages tested. 537. Hill, Walter E. and Fessenden, Ralph J. (1974). Structural studies on the 30 S ribosomal subunit from Escherichia coli. *Journal of Molecular Biology* 90: 719-726.
Chem Codes: Chemical of Concern: PSM Rejection Code: BACTERIA.

Small-angle X-ray scattering curves computed for various 30 S subunit structures have been compared with the experimental scattering curve. The curve from the 30 S subunit is best approximated by that calculated for a 1:3.6:3.6 ellipsoidal structure. The rather prolate ellipsoidal model suggested by recent electron microscope studies gives a scattering curve considerably different from the 30 S curve, suggesting that the electron microscope model is not that found in solution. Analysis of the more extended portions of the experimental scattering curve suggests some internal structure. A model is proposed that contains RNA and protein in positions such that the calculated scattering curve shows more extensive, yet similar internal structure. Resultant constraints on the structure of the 30 S subunit in solution are given.

ABSTRACT: BIOSIS COPYRIGHT: BIOL ABS. To date 23 species of predatory mites of the

family Phytoseiidae (Acari: Mesotigmata) have been recorded on chemically untreated apple trees and vines in Czechoslovakia. Typhlodromus pyri has been found to be the only one abundant species occurring in commercial apple orchards and vineyards. Toxological bioassays have proved a resistance of some local populations of T. pyri from South Bohemia and South Moravia to fenitrothion, phosmet, mevinphos, azinphosethyl, bromopropylate and dicofol. T. puri is also goalseekinglyused as means of biological control of phytophageous mites in commercial apple orchards and vineyards in some fruit and vine growing areas in Czechoslovakia. Potentialities of a practical use of the indigenous predatory phytoseiid mites inhabiting various wild plants as well as imported strange species Amblyseius fallacis and T. occidentalis are discussed. The dissemination of resistant populations of T. pyri into orchards and vineyards is recommended to be

Patent Application Country: Application: US
Priority Application Country: US
Priority Application Number: 2001-345349
Priority Application Date: 20011025 The invention provides fibrous pest deterrents that combine the useful properties of a phys. barrier in the form of a nonwoven fibrous matrix with a chem. deterrent such as a pesticide, behavior-modifying compd. or a pest repellent. The use of such fibrous pest deterrents protects plants, animals and structures in both agricultural and nonagricultural settings from damage inflicted by pests. Unlike traditional pesticides, the behavior-modifying compd., pesticide or chem. deterrent of the invention is adsorbed or attached to a fibrous matrix, and so it is not so readily dispersed into the environment. Hence, use of the fibrous pest deterrents can reduce the levels of pesticides that inadvertently contaminate nontarget areas and pollute water supplies. [on SciFinder (R)] A01N025-34. Citations: 5) US Environmental Protection Agency; Appendix B to 40CFR Part 136 - Definition and procedure for the determination of the method detection limit - Revision 1.11 1984 The method of A. H. Roos et al. (1987), in which size-exclusion chromatog. (SEC) cleanup and high-resoln. gas chromatog. (HRGC) are combined, was adapted to detn. pesticides in kiwifruit. Adding sodium carbonate during extn. reduces levels of acidic interferences and improves recoveries of some basic pesticides such as prochloraz. The SEC cleanup effectively and reproducibly removes lipids, chlorophylls and other high mol. wt. co-extractives that otherwise rapidly lead to reduced HRGC performance. Multi-residue methods such as this remain very dependant on rigid quality control and skilled analysts for their performance, particularly in the HRGC aspects which remain the weakest links. Therefore performance validation is essential to ensure that the method as applied is producing reliable data. Recovery data for surrogate stds. and for low level fortified samples are crucial in this respect. Data on precision and limits of detection for analytes, if gathered on a regular basis, are invaluable for objective validation and tracking the on-going performance of the method. A rapid multiresidue procedure for fruits, based on MeOH extn., is presented. Water and highly water-sol. coextractives are removed by partitioning the pesticides into PhMe. Carbon-cellulose-Florisil cleanup is performed before gas chromatog. on OV-225 with electron capture detection. A wide range of pesticides can be detd. to 0.1 mg/kg without concg. the ext. Gas chromatog. of the crude PhMe partition using SE-30 and an alkali flame ionization detector provides confirmatory data and allows detection of some carbamates. Dichlorvos [62-73-7], dimethoate [60-51-5], and acephate [30560-19-1] are detd. directly in the MeOH ext. by flame photometric detection. High recoveries were obtained for 4 organochlorine insecticides, 13 organophosphorus insecticides, 2 synthetic pyrethroids, two N-Me carbamates, and 10 fungicides. The method is economical of solvents, glassware, and time, and is recommended for routine surveillance of residue levels on fruit. CAS Registry Numbers: 62-73-7; 63-25-2; 133-06-2; 133-07-3; 470-90-6; 732-11-6; 2425-06-1; 2921-88-2; 24017-47-8; 29232-93-7; 38260-54-7; 50471-44-8; 52645-53-1 Role: BIOL (Biological study) (residues of, on kiwifruit) Pesticide decay was studied on kiwifruit (Actinidia chinensis). Residues on the fruit generally followed bimodal 1st-order decay patterns. Initial half-lives in days were: dichlorvos [62-73-7] 0.6-1, pirimiphos-methyl [29232-93-7] 1-2, etrimfos [38260-54-7] 7, captan [133-06-2] 12-21, permethrin [52645-53-1] 14-15, chlorpyrifos [2921-88-2] 8-15, carbaryl [63-25-2] 17, triazophos [24017-47-8] 22, folpet [133-07-3] 17-30, vinclozolin [50471-44-8] 30, chlorfenvinphos [470-90-6] 35, phosmet [732-11-6] 40, and captafol [2425-06-1] 20-48. After 1-3 half-lives, a marked redn. in decay rate occurred and low level residues of most pesticides were very persistent. Residues from applications made close to fruit set were generally less persistent initially than those from main season sprays. Low levels of captan were detectable at harvest, 5 mo following application. [on SciFinder (R)] 0370-2804

A method is described for screening wine for 74 pesticide residues. Aliquots of wine (10 mL) are extd. with 500 mg C18-silica solid-phase extn. (SPE) columns after addn. of carbophenothion internal std. at 0.1 mg/L. The column is washed with 20% EtOH-H2O (4 mL), and pesticide residues are eluted with 1 mL EtOAc. The ext. is made up to 2 mL final vol. with isooctane for screening by gas-liq. chromatog. (GC) using a narrow-bore FSOT column (5% phenyl-95% methyl-silicone bonded phase) with effluent splitting to electron capture (ECD) and N-P detectors. A 2nd GC system, using a 50% phenyl-50% methyl-silicone FSOT column with effluent splitting to ECD and flame photometric detector (P mode), is used for confirmation. The SPE method was rapid, robust, and reproducible. Recovery of pesticides added at 0.2 mg/L were 70-110% for the majority of pesticides, with std. deviations (SDs) of 1-18%. Some highly polar pesticides gave low recoveries. At a fortification level of 1 mg/L in wine, 13 fungicides gave recoveries of 80-118%, with SDs of 2-14%. At 0.02 mg/L, some less stable pesticides exhibited enhanced recoveries due to the protective effects of coextractives during GC. Detection limits were 0.01-0.02 mg/L with no major interferences obsd. from a range of wines. The multiple GC column and detector combinations and the internal std. provided a high degree of assurance in the identification of residues in wine. A multiresidue screen for quant. detn. of 43 organophosphorus Insecticides in 5 g of plant and animal tissues is described. The organophosphorus insecticides are extd. with methanol-dichloromethane (10 + 90, vol./vol.) and cleaned up using automated gel permeation chromatog. with hexane-Et acetate (60 + 40) eluant and in-line silica gel minicolumns. Concd. exts. are anal. by gas chromatog. with flame photometric detection. The method recovers 43 organophosphorus insecticides in the range of 72-115%. Anal. of fortified bovine liver shows an av. 95.9% recovery at the 0.05 mg/g level and 93% at the 0.5 mg/g level. Anal. of fortified bovine rumen content shows an av. 98% recovery at the 0.1 mg/g level and 98.7% at the 1 mg/g level. Method detection limits ranged from 0.01 to 0.05 mg/g for the compds. studied using a nominal 5-g sample. Abstract: The pollen of 30 taxa (27 species, one subspecies and two varieties) in two genera, viz Polygonum s. str. and Polygonella was investigated with LM and SEM, and some selected taxa with TEM. In all genera investigated the pollen is prolate to spheroidal, and the aperture is mostly tricolporate, rarely panto-hexacolporate (especially Polygonum section Polygonum). The exine sculpturing pattern is the most variable feature. Three types of exine can be recognized. Type 1 (Avicularia-Type, sensu Hedberg) - All species of section Polygonum and section Tephis share the smooth tectate exine with spinules, sometimes the surface is more or less rough (Polygonum afromontanum in section Tephis). Type 2 (Pseudomollia-Type, sensu Hong) - Pollen of Polygonum molliaeforme (section Pseudomollia) has the exine, which is verrucose on both poles and nearby the mesocolpium, and mostly psilate around the ectoaperture. Type 3 (Duravia-Type, sensu Hedberg) - Pollen grains of Polygonum section Duravia and Polygonella have the exine which is semitectate-reticulate at the mesocolpium and the poles, and rugulate/reticulate or sometimes foveolate with microspinules around the ectoapertures. The pollen grains in four taxa (viz Polygonum section Pseudomollia, P. section Duravia and genus Polygonella) have a well-marked dimorphism of the ektexine, which is considered to be a synapomorphic condition. The differences of pollen grain between the genus Polygonella and Polygonum section Duravia are almost non existent and clearly interrelated. It is therefore postulated that the similarity in pollen of both taxa is not the result of convergency, but is interpreted as a homology. It is noteworthy that the pollen of Polygonum molliaeforme (section Pseudomollia) appears as intermediate between the Avicularia-type and the Duravia-type, and is well supported the value of separated section for its own. Additionally, in TEM, some exine ultrastructures (e.g. columellae, foot layer, endexine) appear to be valuable characters for comparison between/ among taxa. The systematic potentialities of the pollen data of the studied taxa at various systematic levels are also discussed. (copyright) Springer-Verlag 2005.

Chem Codes: Chemical of Concern: PSM Rejection Code: FATE.

ABSTRACT: BIOSIS COPYRIGHT: BIOL ABS. Leaf litter is an important source of natural dissolved organic carbon (DOC) in forested catchments. Rainwater percolating through fresh litter obtains higher concentrations of DOC and colour than from older forest floor material and organic soils. Chemical characterisation using DOC fractionation and tests of biodegradability show that natural litter percolates contain significant fractions of coloured and highly refractory hydrophobic acids (humic substances) and variable fractions of biodegradable compounds. Deciduous leaf litter imparts high DOC concentrations in the autumn, while coniferous litter and organic soils release DOC more evenly. Leaching from fresh deciduous litter may explain the seasonality in the concentration of DOC in discharge from forested catchments. Countrywide Norwegian data show very poor relationships between occurrences of mires in the catchment of lakes and water colour. High concentrations of DOC may occur in lakes where the catchment has a high proportion of surface runoff due to thin or impermeable soils or swamp areas.

Supercrit. carbon dioxide modified with 3% (vol./vol.) acetonitrile was used to ext. the pesticides at 60 Deg C and sep. the pesticides from the fats at 4000 psi and 95 Deg C on an in-line C1 silica-based column. The extn. and cleanup procedure gave good recoveries for 43 of 62 nonpolar to moderately polar organochlorine and organophosphorus pesticides from fats, whereas 49 were recovered through conventional Florisil column cleanup before quantitation. This procedure can ext. and clean up pesticide residues from 0.65 g animal-based fat and 1.0 g oils. Co-eluted

residues in the pesticide fraction ranged from 2.5 mg for butterfat to 0.8 mg for corn oil. Results for samples analyzed with this integrated extn. cleanup procedure were reproducible and comparable with results obtained with the current Total Diet Study methodol. This column is a replacement for the time-consuming and labor intensive separatory-funnel partition of the Luke procedure. Recoveries from the column are quant. and reproducible for industrial phosphates and a wide range of polar and nonpolar organophosphate pesticides. The column is reusable and convenient and results in a 35-45% savings in time over separatory funnel partition. Neither sulfate columns nor separatory funnels are required, and no emulsions are formed. [on SciFinder (R)] 0004-5756 gas/ chromatog/ organophosphate/ pesticide/ food

In particular, the invention provides a phosphotriesterase enzyme identified from an Agrobacterium radiobacter strain isolated from soil that hydrolyzes organophosphorous pesticides, and the gene opdA encoding that enzyme. The nucleotide sequence of the gene opdA and the amino acid sequence of the encoded phosphotriesterase are provided. The invention also provides mutants of the identified phosphotriesterase enzyme which have altered substrate specificity. The use of these enzymes in bioremediation strategies is also provided. Citations: 44) Zimmerer, R; J Bacteriol 1966, 92, 746 The authors have isolated a bacterial strain, Agrobacterium radiobacter P230, which can hydrolyze a wide range of organophosphate (OP) insecticides. A gene encoding a protein involved in OP hydrolysis was cloned from A. radiobacter P230 and sequenced. This gene (called opdA) had sequence similarity to opd, a gene previously shown to encode an OP-hydrolyzing enzyme in Flavobacterium sp. strain ATCC 27551 and Brevundimonas diminuta MG. Insertional mutation of the opdA gene produced a strain lacking the ability to hydrolyze OPs, suggesting that this is the only gene encoding an OP-hydrolyzing enzyme in A. radiobacter P230. The OPH and OpdA proteins, encoded by opd and opdA, resp., were overexpressed and purified as maltose-binding proteins, and the maltose-binding protein moiety was cleaved and removed. Neither protein was able to hydrolyze the aliph. OP malathion. The kinetics of the two proteins for di-Et OPs were comparable. For di-Me OPs, OpdA had a higher kcat than OPH. It was also capable of hydrolyzing the di-Me OPs phosmet and fenthion, which were not hydrolyzed at detectable levels by OPH. [on SciFinder (R)] 0099-2240

Citations: 11) Solsky, J; Questionable Practices in the Laboratory, 14th Annual Waste Testing & Quality Assurance Symposium 1998 Proficiency studies have been suggested as an alternative source of information for evaluating method performance characteristics when results from interlab. method performance studies conforming to internationally recognized protocols are not available. To explore this possibility, results were examd. from ongoing proficiency studies of pesticide residue analyses in celery, carrot, and grape purees, and in wine. Statistical performance parameters were calcd. from 18 data sets analyzed as unknowns by about 60 analysts for 12

analytes in the 25-1000 mg/kg range, and from presumably parallel control (spike) analyses conducted by about half of the participants. Recovery of known, independent control addns. by the participant did not correlate with the recoveries detd. as unknowns in the exercise. The data suggest that censoring or truncating of control data has occurred. The question of substitution of proficiency data for method performance data cannot be answered until the problem of unbiased reporting of control data is resolved. Chem Codes: Chemical of Concern: PSM Rejection Code: MODELING.

A new expression for a geometric factor for ellipsoid shapes is developed by applying semi-analytical solutions of phase-change problems with convective cooling at the surface. Testing against finite element predictions for prolate and oblate spheroids showed that the new formula is more accurate than any alternative shape factor for practical ranges of conditions. By use of a model ellipsoid defined as having the same volume, characteristics dimension and smallest orthogonal cross-sectional area as the actual shape in conjunction with the proposed shape factor, published experimental freezing and thawing times of three-dimensional irregular shapes are more accurately predicted that by any other shape factor. freezing times/ thawing times/ mathematical model/ temps de congelation/ entreposage d'aliments/ modele mathematique

A rapid multiscreen method for 110 pesticides was applied to fruits and vegetables. Samples were extd. and residues were evaluated routinely within 6.5 h of receipt. Organochlorine pesticides were detd. by gas chromatog. on DB-603 and DB-5 columns with electron-capture detection. Organophosphorus pesticides were detd. by gas chromatog. on DB-5 or DB-1701 columns with alkali flame-ionization and flame-photometric detectors, resp. Carbamates were detd. by HPLC on a Waters Carbamate Anal. column with fluorescence detection. Subsequent confirmation of identity was made by gas chromatog.-mass spectrometry. Citations: 2) Chen, G; Proceedings Electrochemical Society 2001-18 A lateral field excited (LFE) acoustic wave sensor has been developed in which the sensing surface is bare and the elec. excitation is applied on the bottom surface. The LFE sensor has been used as the sensing platform to detect the pesticide, phosmet (C11H12NO4PS2). A polyepichlorohydrin (PECH) polymer film is applied to the sensing surface to detect the pesticide phosmet in deionized water. The PECH

coated LFE sensor displays a nearly linear response to the injection of the phosmet with a slope of 106Hz/ppm and a sensitivity in the ppb range. [on SciFinder (R)] pesticide/ detection/ lateral/ field/ excited/ acoustic/ sensor

565. Huang, Jen-How and Matzner, Egbert (Fluxes of inorganic and organic arsenic species in a Norway spruce forest floor. *Environmental Pollution* In Press, Corrected Proof: 1019.
Chem Codes: Chemical of Concern: PSM Rejection Code: FATE.

To identify the role of the forest floor in arsenic (As) biogeochemistry, concentrations and fluxes of inorganic and organic As in throughfall, litterfall and forest floor percolates at different layers were investigated. Nearly 40% of total Astotal input (5.3 g As ha-1 yr-1) was retained in Oi layer, whereas Astotal fluxes from Oe and Oa layers exceeded the input by far (10.8 and 20 g As ha-1 yr-1, respectively). Except dimethylarsinic acid (DMA), fluxes of organic As decreased with depth of forest floor so that <10% of total deposition (all <0.3 g As ha-1 yr-1) reached the mineral soil. All forest floor layers are sinks for most organic As. Conversely, Oe and Oa layers are sources of Astotal, arsenite, arsenate and DMA. Significant correlations (r >= 0.43) between fluxes of Astotal, arsenite, arsenate or DMA and water indicate hydrological conditions and adsorption-desorption as factors influencing their release from the forest floor. The higher net release of arsenite from Oe and Oa and of DMA from Oa layer in the growing than dormant season also suggests microbial influences on the release of arsenite and DMA. The multi-residue anal. of the pesticides in teas involved extn. with acetone-Et acetate-hexane, clean-up using gel permeation chromatog. (GPC) and solid-phase extn. (SPE), and subsequent identification and quantification of the selected pesticides by gas chromatog.-mass spectrometry (GC-MS) under retention time locked (RTL) conditions. For most of the target analytes, the optimized pretreatment processes led to no significant interference on anal. from sample matrix, and the detn. of 102 compds. was achieved in about 120 min. Pesticide residues could be detd. in low sub-ppb range, from 0.01 mg/mL for hexachlorobenzene to 2.5 mg/mL for propargite, with av. recoveries ranging from 59.7 to 120.9% (mean 88%) and relative std. deviations (RSDs) in the range 3.0-20.8% (mean 13.7%) for all analytes across 3 fortification tea levels. The limits of detection (LODs) were much lower than the max. residue levels established by the European Union (EU) legislations. Priority Application Country: US
Priority Application Number: 2003-443256
Priority Application Date: 20030128 The title compds. [I; R1 = Me, Cl, Br, F; R2 = F, Cl, Br, haloalkyl or haloalkoxy; R3 = F, Cl, Br; R4 = H, alkyl, alkenyl, alkynyl, cycloalkyl, cycloalkylalkyl, each optionally substituted with one substituent selected from the group consisting of halo, CN, SMe S(O)Me, S(O)2Me and OMe; R5 = H, Me; R6 = H, F, Cl; R7 = H, F, Cl], useful for controlling an invertebrate pest, were prepd. E.g., a multi-step synthesis of compd. I [R1 = Me; R2 = CF3; R3 = Cl; R4, R5 = H], was given. The compds. I were tested in various biol. tests (data given). This invention also pertains to a compn. for controlling an invertebrate pest comprising a biol. effective amt. of a compd. I, an N-oxide thereof or a suitable salt of the compd. I and at least one addnl. component selected from the group consisting of a surfactant, a solid diluent and a liq. diluent. Index Terms: Prostate gland (benign hyperplasia; human toxicol. effect and damage factors of carcinogenic and noncarcinogenic chems. for life cycle impact assessment); Hyperplasia (benign prostatic; human toxicol. effect and damage factors of carcinogenic and noncarcinogenic chems. for life cycle impact assessment); Mental and behavioral disorders (bipolar disorder; human toxicol. effect and damage factors of carcinogenic and noncarcinogenic chems. for life cycle impact assessment); Ischemia (cardiac; human toxicol. effect and damage factors of carcinogenic and noncarcinogenic chems. for life cycle impact assessment); Inflammation (carditis; human toxicol. effect and damage factors of carcinogenic and noncarcinogenic chems. for life cycle impact assessment); Brain (cerebrovascular; human toxicol. effect and damage factors of carcinogenic and noncarcinogenic chems. for life cycle impact assessment); Uterus (cervix; human toxicol. effect and damage factors of carcinogenic and noncarcinogenic chems. for life cycle impact assessment); Paraffin waxes Role: ADV (Adverse effect, including toxicity), BIOL (Biological study) (chloro; human toxicol. effect and damage factors of carcinogenic and noncarcinogenic chems. for life cycle impact assessment); Lung (chronic obstructive pulmonary disease; human toxicol. effect and damage factors of carcinogenic and noncarcinogenic chems. for life cycle impact assessment); Coal tar Role: ADV (Adverse effect, including toxicity), BIOL (Biological study) (coke overemissions; human toxicol. effect and damage factors of carcinogenic and noncarcinogenic chems. for life cycle impact assessment); Intestine (colon; human toxicol. effect and damage factors of carcinogenic and noncarcinogenic chems. for life cycle impact assessment); Life (cycle; human toxicol. effect and damage factors of carcinogenic and noncarcinogenic chems. for life cycle impact assessment); Mental and behavioral disorders (dementia; human toxicol. effect and damage factors of carcinogenic and noncarcinogenic chems. for life cycle impact assessment); Disease (digestion disorder; human toxicol. effect and damage factors of carcinogenic and noncarcinogenic chems. for life cycle impact assessment); Digestion (disease; human toxicol. effect and damage factors of carcinogenic and noncarcinogenic chems. for life cycle impact assessment); Vitamins Role: ADV (Adverse effect, including toxicity), BIOL (Biological study) (fat-sol.; human toxicol. effect and damage factors of carcinogenic and noncarcinogenic chems. for life cycle impact assessment); Trace metals Role: ADV (Adverse effect, including toxicity), BIOL (Biological study) (heavy; human toxicol. effect and damage factors of carcinogenic and noncarcinogenic chems. for life cycle impact assessment); Steroids Role: ADV (Adverse effect, including toxicity), BIOL (Biological study) (hormones; human toxicol. effect and damage factors of carcinogenic and noncarcinogenic chems. for life cycle impact assessment); Anesthetics; Antibiotics; Asthma; Bladder; Bronchi; Carcinogens; Cardiovascular system; Cataract; Cirrhosis; Congenital malformations; Cytotoxic agents; Diabetes mellitus; Drug toxicity; Dyes; Epilepsy; Esophagus; Fungicides; Glaucoma; Herbicides; Human; Insecticides; Kidney; Leukemia; Liver; Lung; Lymphoma; Mammary gland; Melanoma; Mouth; Multiple myeloma; Multiple sclerosis; Muscle; Mutagens; Natural products; Neoplasm; Osteoarthritis; Ovary; Pancreas; Parkinson's disease; Parturition; Pesticides; Prostate gland; Respiratory system; Rheumatoid arthritis; Risk assessment; Schizophrenia; Skeleton; Skin; Solvents; Stomach; Toxicants; Toxicity; Urinary system; Uterus (human toxicol. effect and damage factors of carcinogenic and noncarcinogenic chems. for life cycle impact assessment); Aflatoxins; Alcohols; Aldehydes; Amino acids; Insect-molting hormones; Mycotoxins; Pyrethrins; Rare earth metals; Tocopherols; Toxins; Vitamins Role: ADV (Adverse effect, including toxicity), BIOL (Biological study) (human toxicol. effect and damage factors of carcinogenic and noncarcinogenic chems. for life cycle impact assessment); Toxicity (inhalation; human toxicol. effect and damage factors of carcinogenic and noncarcinogenic chems. for life cycle impact assessment); Heart (ischemia; human toxicol. effect and damage factors of carcinogenic and noncarcinogenic chems. for life cycle impact assessment); Heart; Inflammation (myocarditis; human toxicol. effect and damage factors of carcinogenic and noncarcinogenic chems. for life cycle impact assessment); Trachea (neoplasm; human toxicol. effect and damage factors of carcinogenic and noncarcinogenic chems. for life cycle impact assessment); Inflammation; Kidney (nephritis; human toxicol. effect and damage factors of carcinogenic and noncarcinogenic chems. for life cycle impact assessment); Mental and behavioral disorders (obsession-compulsion; human toxicol. effect and damage factors of carcinogenic and noncarcinogenic chems. for life cycle impact assessment); Insecticides (organochlorine; human toxicol. effect and damage factors of carcinogenic and noncarcinogenic chems. for life cycle impact assessment); Insecticides

(organophosphorus; human toxicol. effect and damage factors of carcinogenic and noncarcinogenic chems. for life cycle impact assessment); Pharynx (oropharynx; human toxicol. effect and damage factors of carcinogenic and noncarcinogenic chems. for life cycle impact assessment); Anxiety (panic disorder; human toxicol. effect and damage factors of carcinogenic and noncarcinogenic chems. for life cycle impact assessment); Ulcer (peptic; human toxicol. effect and damage factors of carcinogenic and noncarcinogenic chems. for life cycle impact assessment); Medicine (psychiatry, neuropsychiatry; human toxicol. effect and damage factors of carcinogenic and noncarcinogenic chems. for life cycle impact assessment); Intestine (rectum; human toxicol. effect and damage factors of carcinogenic and noncarcinogenic chems. for life cycle impact assessment); Heart (rheumatic; human toxicol. effect and damage factors of carcinogenic and noncarcinogenic chems. for life cycle impact assessment); Organ (sense organ; human toxicol. effect and damage factors of carcinogenic and noncarcinogenic chems. for life cycle impact assessment); Organ (sensory, disease; human toxicol. effect and damage factors of carcinogenic and noncarcinogenic chems. for life cycle impact assessment); Hormones Role: ADV (Adverse effect, including toxicity), BIOL (Biological study) (steroid; human toxicol. effect and damage factors of carcinogenic and noncarcinogenic chems. for life cycle impact assessment); Heavy metals Role: ADV (Adverse effect, including toxicity), BIOL (Biological study) (trace; human toxicol. effect and damage factors of carcinogenic and noncarcinogenic chems. for life cycle impact assessment); Neoplasm (tracheal; human toxicol. effect and damage factors of carcinogenic and noncarcinogenic chems. for life cycle impact assessment); Digestive tract (ulcer, peptic; human toxicol. effect and damage factors of carcinogenic and noncarcinogenic chems. for life cycle impact assessment)
CAS Registry Numbers: 7439-97-6D (Mercury) Role: ADV (Adverse effect, including toxicity), BIOL (Biological study) (f; human toxicol. effect and damage factors of carcinogenic and noncarcinogenic chems. for life cycle impact assessment); 50-00-0 (Formaldehyde); 50-06-6 (Phenobarbital); 50-07-7 (Mitomycin-C); 50-18-0 (Cyclophosphamide); 50-24-8 (Prednisolone); 50-29-3 (DDT); 50-32-8 (Benzo[a]pyrene); 50-33-9 (Phenylbutazone); 50-55-5 (Reserpine); 50-76-0 (Actinomycin D); 51-03-6 (Piperonyl butoxide); 51-21-8 (5-Fluorouracil); 51-28-5 (2,4-Dinitrophenol); 51-52-5 (Propylthiouracil); 51-75-2; 51-79-6 (Urethane); 52-24-4 (Thio-tepa); 52-68-6 (Trichlorfon); 52-76-6 (Lynestrenol); 53-43-0 (Dehydroepiandrosterone); 53-70-3 (Dibenz[a,h]anthracene); 53-86-1 (Indomethacin); 53-95-2 (N-Hydroxy-2-acetylaminofluorene); 53-96-3 (2-Acetylaminofluorene); 54-31-9 (Furosemide); 54-85-3 (Isoniazid); 55-18-5 (N-Nitrosodiethylamine); 55-38-9 (Fenthion); 55-63-0 (Trinitroglycerin); 55-80-1 (3'-Methyl-4-dimethylamino-azobenzene); 56-04-2 (Methylthiouracil); 56-23-5 (Carbon tetrachloride); 56-35-9 (Tributyltin-oxide); 56-38-2 (Parathion); 56-40-6 (Glycine); 56-49-5 (3-Methylcholanthrene); 56-53-1 (Diethylstilbestrol); 57-06-7 (Allyl isothiocyanate); 57-12-5 (Cyanide); 57-14-7 (1,1-Dimethylhydrazine); 57-24-9 (Strychnine); 57-30-7 (Phenobarbital, sodium); 57-39-6 (Metepa); 57-41-0 (5,5-Diphenylhydantoin); 57-57-8 (b-Propiolactone); 57-63-6 (Ethinyl estradiol); 57-66-9 (Probenecid); 57-68-1 (Sulfamethazine); 57-97-6; 58-89-9 (g-1,2,3,4,5,6-Hexachlorocyclo-hexane); 58-90-2 (2,3,4,6-Tetrachlorophenol); 59-33-6 (Pyrilamine maleate); 59-35-8 (4,6-Dimethyl-2-(5-nitro-2-furyl)pyrimidine); 59-87-0 (5-Nitro-2-furaldehyde semicarbazone); 59-88-1 (Phenylhydrazine hydrochloride); 59-89-2 (N-Nitrosomorpholine); 60-11-7; 60-29-7 (Ethyl ether); 60-34-4 (Methylhydrazine); 60-35-5 (Acetamide); 60-51-5 (Dimethoate); 60-56-0 (Methimazole); 60-57-1 (Dieldrin); 60-80-0 (Phenazone); 61-82-5 (3-Aminotriazole); 61-94-9 (Arecoline hydrochloride); 62-23-7 (p-Nitrobenzoic acid); 62-38-4 (Phenylmercuric acetate); 62-44-2 (Phenacetin); 62-53-3 (Aniline); 62-55-5 (Thioacetamide); 62-56-6 (Thiourea); 62-73-7 (Dichlorvos); 62-74-8 (Sodium fluoroacetate); 62-75-9 (N-Nitrosodimethylamine); 63-25-2 (Carbaryl); 63-92-3 (Phenoxybenzamine hydrochloride); 64-17-5 (Ethyl alcohol); 65-85-0 (Benzoic acid); 66-22-8 (Uracil); 66-27-3 (Methyl methanesulfonate); 67-20-9 (1-[(5-Nitrofurfurylidene)amino]hydantoin); 67-21-0 (DL-Ethionine); 67-56-1 (Methanol); 67-64-1 (Acetone); 67-66-3 (Chloroform); 67-72-1 (Hexachloroethane); 68-12-2 (Dimethylformamide); 68-76-8 (Trenimon); 68-89-3 (Dipyrone); 70-25-7 (N-Methyl-N'-nitro-N-nitrosoguanidine); 70-30-4 (Hexachlorophene); 71-36-3 (Butanol); 71-43-2 (Benzene); 72-20-8 (Endrin); 72-43-5 (Methoxychlor); 72-54-8; 72-55-9; 74-83-9 (Bromomethane); 74-87-3 (Methyl chloride); 74-90-8 (Hydrogen cyanide); 74-96-4 (Bromoethane); 75-00-3 (Chloroethane); 75-01-4 (Vinyl chloride); 75-02-5 (Vinyl fluoride); 75-05-8 (Acetonitrile); 75-07-0 (Acetaldehyde); 75-09-2 (Methylene

chloride); 75-15-0 (Carbon disulphide); 75-21-8 (Ethylene oxide); 75-25-2 (Tribromomethane); 75-27-4 (Bromodichloromethane); 75-35-4 (Vinylidene chloride); 75-37-6 (HFC-152a); 75-45-6 (Freon-22); 75-52-5 (Nitromethane); Citations: Wilkinson, C; Regul Toxicol Pharmacol 2000, 31, 30 Chem. fate, effect, and damage should be accounted for in the anal. of human health impacts by toxic chems. in life cycle assessment (LCA). The goal of this article is to present a new method to derive human damage and effect factors of toxic pollutants, starting from a lognormal dose-response function. Human damage factors are expressed as disability-adjusted life-years (DALYs). Human effect factors contain a disease-specific and a substance-specific component. The disease-specific component depends on the probability of disease occurrence and the distribution of sensitivities in the human population. The substance-specific component, equal to the inverse of the ED50, represents the toxic potency of a substance. The new method has been applied to calc. combined human damage and effect factors for 1192 substances. The total range of 7-9 orders of magnitude between the substances is dominated by the range in toxic potencies. For the combined factors, the typical uncertainty, represented by the square root of the ratio of the 97.5th and 2.5th percentiles, is a factor of 25 for carcinogenic effects and a factor of 125 for noncarcinogenic effects. The interspecies conversion factor, the (non)cancer effect conversion factor, and the av. noncancer damage factor dominate the overall uncertainty. 570. Humeniuk, R. E., Ong, J., Kerr, D. I., and White, J. M. (Characterization of Gabab Ligands in Vivo. *Gen pharmacol. 1995, mar; 26(2):417-24. [General pharmacology]: Gen Pharmacol.*
<u>Chem Codes</u>: Chemical of Concern: PSM <u>Rejection Code</u>: HUMAN HEALTH.

ABSTRACT: 1. While GABAB antagonists have been examined in vitro, very few have been tested in vivo. A range of GABAB antagonists were tested against baclofen-induced muscle relaxation and hypothermia. 2. The GABAB antagonists exhibited a range of in vivo activity profiles. 3. CGP 35348 showed clear antagonist effects, while BPBA and 4-ABPA appeared to have agonist properties. 4. Phaclofen, 2-hydroxysaclofen, 3-APPA and 9G seemed to have little effect in this system at the doses tested. 5. Differences between in vivo and in vitro activity could be explained by differences in blood-brain barrier permeability, or possible differences in affinities for the sub-classes of GABAB receptors.

ABSTRACT: This article represents the proceedings of a symposium at the 2001 annual meeting of the Research Society on Alcoholism in Montreal, Canada. The chairpersons were Appa Hungund and George Koob. The presentations were (1) Role of endocannabinoids in ethanol tolerance, by Appa Hungund; (2) Modulation of cannabinoid receptor and its signal transduction in chronic alcoholism, by B. S. Basavarajappa; (3) Endocannabinoid involvement in the control of appetitive behavior, by George Kunos; (4) Regulation of voluntary ethanol intake by cannabinoid receptor agonists and antagonists in alcohol-preferring sP rats, by Giancarlo Colombo; (5) Role of endogenous cannabinoid system in alcoholism, by Fernado Rodriguez de Fonseca; and (6) Endocannabinoids and dopamine interactions in vivo, by Loren Parsons and George Koob.

Chem Codes: Chemical of Concern: PSM Rejection Code: CHEM METHODS.

4,4-Dimethyl-2,5-cyclohexadien-1-one has been prepared by a three-step reaction from 4,4-dimethyl-2-cyclohexen-1-one. Microwave transitions of the cross-conjugated compound have been measured over extended regions from 11 to 40 GHz. The spectrum is a classical a-type spectrum of a near-prolate top with many interspersed lines presumably originating from excited vibrational states. No internal rotation splitting could be observed. We were able to assign 108 rotational transitions with J-quantum numbers up to 40. The least-squares fit showed a standard deviation of 30 kHz and yielded the three rotational constants, A = 3332.158(13) MHz, B = 1193.07386(52) MHz, C = 1082.21280(45) MHz, as well as all five quartic centrifugal distortion constants from Watson's A-reduction: [Delta]J = 0.02149(73) kHz, [Delta]JK = 1.1008(16) kHz, [Delta]K = -68.42(32) kHz, [delta]J = 0.00332(16) kHz, [delta]K = -2.7513(99) kHz (representation IR used). The dipole moment was determined from the Stark shift of the M-components of two transitions and was found to be 4.4522(83) D from 93 measurements.

Based on the atom-type electrotopol. state (E-state) indexes, a quant. structure-property relationship model for the prediction of aq. soly. for a diverse set of 745 org. compds. is presented. The multiple linear regression anal. was used to build the models. A training set of 674 compds., contg. 349 liqs. and 325 solids and with a range of aq. soly. (log S) from 2.77 to -11.62, was obtained from the literature. For this set, the squared correlation coeff. and std. deviation for a linear model with 31 atom-type E-state indexes and 3 simple correction factors were r2 =0.94 and s =0.58 (log units), resp. The corresponding statistics for the test sets not included in the training set were, for a set of 50 pesticides, r2 =0.79 and s =0.81 and, for a set of 21 drug and pesticide compds., r2 =0.83 and s =0.84, resp. The contribution of m.ps. was also evaluated. The use of m.p. increased the accuracy of the models in the fit of the training set but not in the prediction of the test sets. Hence, the

proposed method offers fast and accurate estn. of aq. soly. of org. compds. using atom-type E-state indexes without the need of any exptl. parameters like the m.ps. [on SciFinder (R)] 0730-7268

Using a training set of 403 compds., in which the log Koc values were in the range 0-6.5, multiple linear regression (MLR) was utilized to build the models. The models were validated using a test set of 165 chems. not included in the training set. The statistics for a linear regression model with calcd. aq. soly., log S, were r2 = 0.80 and s = 0.51 in the training set, and r2 = 0.76 and s = 0.61 in the test set. The model parameters used allow rapid and accurate calcn. of log Koc values for a diverse set of org. chems., and propose the importance of mol. soly., lipophilicity, size, flexibility, and ionization for a chems.' sorption to org. soil material. 577. Igamberdiev, Abir U. (1999). Foundations of metabolic organization: coherence as a basis of computational properties in metabolic networks. *Biosystems* 50: 1-16.
<u>Chem Codes</u>: Chemical of Concern: PSM <u>Rejection Code</u>: CHEM METHODS.

Biological organization is based on the coherent energy transfer allowing for macromolecules to operate with high efficiency and realize computation. Computation is executed with virtually

100% efficiency via the coherent operation of molecular machines in which low-energy recognitions trigger energy-driven non-equilibrium dynamic processes. The recognition process is of quantum mechanical nature being a non-demolition measurement. It underlies the enzymatic conversion of a substrate into the product (an elementary metabolic phenomenon); the switching via separation of the direct and reverse routes in futile cycles provides the generation and complication of metabolic networks (coherence within cycles is maintained by the supramolecular organization of enzymes); the genetic level corresponding to the appearance of digital information is based on reflective arrows (catalysts realize their own self-reproduction) and operation of hypercycles. Every metabolic cycle via reciprocal regulation of both its halves can generate rhythms and spatial structures (resulting from the temporally organized depositions from the cycles). Via coherent events which percolate from the elementary submolecular level to organismic entities, self-assembly based on the molecular complementarity is realized and the dynamic informational field operating within the metabolic network is generated. 578. Igathinathane, C. and Chattopadhyay, P. K. (1999). Moisture diffusion modelling of drying in parboiled paddy components. Part II: Bran and Husk. *Journal of Food Engineering* 41: 89-101.
Chem Codes: Chemical of Concern: PSM Rejection Code: CHEM METHODS.

Multi-component prolate spheroid geometry was used in developing a non-dimensional isothermal liquid diffusion drying model for studying the moisture movement in the composite solids using a prolate spheroidal co-ordinate system. The developed models were solved using a finite difference method and were applied to simulate the drying process of multi-component parboiled brown rice and parboiled paddy. The observed drying characteristics of the input materials prepared by suitable hydrothermal treatment were obtained using a fluidised bed dryer at drying air temperatures ranging from 50[ring operator]C to 100[ring operator]C. In the multi-component parboiled brown rice drying model, the diffusion coefficients of bran were determined from the diffusion coefficients of the starchy endosperm, and for the parboiled paddy model the diffusion coefficients of husk were determined from the values of starchy endosperm and bran successively. By minimising the sum of squared differences (SSD) between experimentally observed and model predicted characteristics the liquid diffusion coefficients of bran and husk were determined at the various air temperatures studied. The developed models showed good agreement with the observed drying characteristics of the input materials. The temperature dependence of the diffusion coefficients of the parboiled paddy components was expressed by Arrhenius type of equationsThe diffusion coefficients of the parboiled paddy components were comparable to the recent findings on raw paddy and the differences encountered may be attributed to the properties of the component material. http://www.sciencedirect.com/science/article/B6T8J-3X5HD4R-2M/2/4c2edb12eada467a8042501f84fef69e

579. Igathinathane, C. and Chattopadhyay, P. K. (1998). Numerical Techniques for Estimating the Surface Areas of Ellipsoids Representing Food Materials. *Journal of Agricultural Engineering Research* 70: 313-322.
Chem Codes: Chemical of Concern: PSM Rejection Code: CHEM METHODS.

Food materials (seeds, grains, fruits and vegetables) resembling the shape of a general ellipsoid were modelled for accurate determination of surface area from measurements of their three principal dimensions. The process of surface area estimation involved partitioning the ellipsoid into an appropriate number of elliptical discs, determination of the surface areas of the edges of the discs and summing them to obtain the total surface area. Two types of perimeters were used to determine the edge surface areas: (1) the average perimeter; and (2) the root mean square perimeter. For edge length, three measures were considered: (1) parallel to the axis; (2) inclined to the axis; and (3) length of the elliptical arc. Six different surface area models were developed by combining the two perimeters with the three edge lengths and these were validated against exact analytical solutions for a sphere, prolate spheroid and oblate spheroid. The models with parallel edge length always produced the greatest underestimate of surface area and they cannot, in fact, give accurate results, even if a large number of discs is used. The models with inclined and elliptic arc edge length performed well in the entire range of width/length of prolate spheroids and thickness/length of oblate spheroids. For practical computations involving the general ellipsoid, a minimum of 100 discs was found to be sufficient, as it produced a maximum deviation of less than +/-0[middle dot]1% from 1000 discs for all the models and geometries considered. The performances of two approximate formulae for the surface area of the general ellipsoid were also studied for comparison but they were suitable only in the near-spherical range. Predictions were made and compared with the reported surface areas for a few paddy varieties, which were experimentally determined by previous researchers, and were found to deviate within +7[middle dot]0 to +30[middle dot]0%. http://www.sciencedirect.com/science/article/B6WH1-45J55HW-1M/2/dad1fb726569d6b002e519f8165afe92

580. Igathinathane, C. and Chattopadhyay, P. K. (1998). On the development of a ready reckoner table for evaluating surface area of general ellipsoids based on numerical techniques. *Journal of Food Engineering* 36: 233-247.
Chem Codes: Chemical of Concern: PSM Rejection Code: CHEM METHODS.

Surface areas of food materials resembling general ellipsoids can be obtained from the principal dimensions by numerical techniques. Nodes were identified on the surface along the principal planes in the developed model for generating a series of flat triangular element grids and their assembly gave the surface area of the ellipsoidal material. The model was validated against simpler geometries, such as sphere, prolate spheroids and oblate spheroids, and was found to be accurate. With the combination of non-dimensional input in the model and scaling factor a two-dimensional ready reckoner table of reduced surface areas was developed, which covered the entire range of sizes and shapes of general ellipsoid. The method of obtaining the intermediate values in the table by univariate and bivariate linear interpolation was also outlined and the interpolation error was in the range of 0.0-0.57%. The nomogram representation of the table can be utilised for rough estimates. The actual surface area of the object is obtained from the reduced surface area by multiplying it by the scaling factor.

581. Igathinathane, C. and K. Chattopadhyay, P. (1999). Moisture diffusion modelling of drying in parboiled paddy components. Part I: starchy endosperm. *Journal of Food Engineering* 41: 79-88.
Chem Codes: Chemical of Concern: PSM Rejection Code: CHEM METHODS.

A non-dimensionalised isothermal liquid diffusion drying model in prolate spheroid geometry using prolate spheroidal co-ordinate system was developed, and applied to drying of parboiled polished rice. Using appropriate hydrothermal treatment the parboiled polished rice was prepared, and its drying characteristics were determined using fluidised bed drying at air temperatures varying from 50 to 100[ring operator]C. A mathematical model simulating the drying was solved using the finite difference methodology. The liquid diffusion coefficients of starchy endosperm of parboiled polished rice while drying with various air temperatures were determined by minimising the sum of squared differences between experimentally observed and model predicted characteristics. The developed models showed good agreement with the experimentally observed data. Temperature dependence of liquid diffusion coefficients was expressed by an Arrhenius type of equation, which had a high correlation coefficient:

Chem Codes: Chemical of Concern: PSM Rejection Code: HUMAN HEALTH.

ABSTRACT: PESTAB. The organic insecticides phosalone and phthalophos were added to human cadaveric liver preserved with ethyl alcohol and left at room temperature. After 30 days, 31% of the initial phosalone quantity was detectable, and 10.5% was detected after five months. Corresponding values for phthalophos were 23 and 7%, respectively. The addition of ethyl alcohol does improve the conservability of these substances in cadaveric material.

ABSTRACT: PESTAB The preserving effect of ethanol on the stability of phosalone and phthalophos (phosmet) in cadaver liver was studied by photoelectrocolorimetric residue analysis. The preservation of the cadaver tissue with ethanol resulted in increased persistence of both the phosalone and phthalophos residues. After 30 days of preservation in ethanol at room temperature, 31% of the initial phosalone content was detected and fell to 10. 5% in 150 days. The corresponding percentages of phthalophos, recovered after 30 and 150 days, were 23% and 7%, respectively.

587. Imai, A., Fukushima, T., Matsushige, K., and Kim, Y. H. (Fractionation and Characterization of Dissolved Organic Matter in a Shallow Eutrophic Lake, Its Inflowing Rivers, and Other Organic Matter Sources. *Water res. 2001, dec; 35(17):4019-28. [Water research]: Water Res*.
Chem Codes: Chemical of Concern: PSM Rejection Code: FATE, CHEM METHODS.

ABSTRACT: Dissolved organic matter (DOM) in water from eutrophic Lake Kasumigaura, its inflowing rivers, and several other DOM sources in the lake catchment area was fractionated using resin adsorbents into five classes: aquatic humic substances (AHS), hydrophobic neutrals (HoN), hydrophilic acids (HiA), bases (BaS), and hydrophilic neutrals (HiN). The DOM-fraction distribution pattern and the ultraviolet absorbance to dissolved organic carbon ratio (UV/DOC ratio) were found remarkably effective for evaluating the characteristics of DOM in water. DOM-fraction distribution patterns were significantly different depending on the origin of the sample. AHS and HiA were found to be the dominant fractions in DOM in all samples studied. HiA

prevailed over AHS in the lake water, whereas AHS were slightly more abundant than HiA in the river waters. AHS were in the great majority in forest streams and plowed-field percolates. HiA abounded in paddy-field outflow, domestic sewage, and sewage-treatment-plant effluent. Only domestic sewage contained a significant amount of HoN. The UV/DOC ratio also varied depending on the origin of the sample: the ratios in total DOM, AHS, and HiA were greater in river waters than in the lake water. The greatest ratio of AHS was found in paddy-field outflow and the lowest in domestic sewage. The UV/DOC ratios in the sewage-treatment-plant effluent were very similar to those in the lake water.

Chem Codes: Chemical of Concern: PSM Rejection Code: BACTERIA.

1. 1. In order to determine the molecular weight of the crystalline proteinase of Pseudomonas aeruginosa (IFO 3080) sedimentation-velocity experiments have been carried out.2. 2. The boundary-gradient curves obtained have been analysed according to theory. The sedimentation coefficient s0 and the diffusion coefficient D0 at infinite dilution are thus calculated to be 3.99[middle dot]10-13 sec, and 7.4[middle dot]10-7 cm2/sec. respectively.3. 3. Insertion of the above values into the equation gives a mol. wt. of 48 400.4. 4. On the assumption that the proteinase molecule is a rigid ellipsoid of revolution, hydrated to 30%, the molecular dimensions are calculated as follows: a axis 35 A, b axis 68 A for an oblate ellipsoid; a axis 86 A, b axis 43 A for a prolate ellipsoid. http://www.sciencedirect.com/science/article/B73GF-48SJP7F-H/2/179022020e4d424f7df3a01b032e708e

590. Ishige, T. and Uchida, A. (Results of Health Examinations of Pear Farmers in Chiba Prefecture, With Particular Reference to Eeg Findings in (Pesticide) Speed Sprayer Operators. *Nippon noson igakkai zasshi (j. Jpn. Assoc. Rural med.) 25(3): 198-199; 1976.*
Chem Codes: Chemical of Concern: PSM Rejection Code: HUMAN HEALTH.

ABSTRACT: PESTAB. Health examinations were performed on pear farmers in Chiba prefecture in 1975. Complaints of fatigue, stiff shoulders, and lumbago were more frequent in women than in men. Hypertension was recorded in 15.4% of the men and 22.2% of the women. Abnormal electrocardiograms were found in 35.9% of the men and 16.7% of the women. Anemia was noted in 5.1% of the men and 16.7% of the women. Abnormal liver function was detected infrequently, as were glycosuria and proteinuria. EEG studies were performed on seven speed sprayer operators employed in this capacity for 3-4 years, and working in this capacity for 15-25 days in 1975. The average number of hours worked per day was 9, and the principal pesticides applied were fenitrothion, estox, diazinon, imidan, dichlorvos, benomyl, thiophanate-methyl, zineb, dicofol, and machine oil. Four borderline abnormal cases were noted, and two abnormal EEGs, including one severe case. The results of a second EEG study on the same operators in 1976 and on eight new operators showed a slight aggravation of findings in experienced operators and slight abnormalities in the new operators (2 borderline cases and one abnormal).

ABSTRACT: PESTAB. Toxicity of the juvenile hormone analog diflubenzuron (1-(2-6-difluorobenzoyl)-3(4-chlorophenyl)-urea) to house fly larvae resistant to various insecticides was studied. Diflubenzuron at 0.00005-.01% concentrations resulted in the death of 31-87% of larvae of the sensitive strain. Strains resistant to phthalophos (phosmet), Koral (coumaphos), chlorophos (trichlorfon), malathion, neopinamine, and Gardonna (tetrachlorvinphos) were also resistant to diflubenzuron at 0.015-1% concentrations.

In a simple procedure involving exposure to sunlight for up to 1 hr, 28 candidate sensitizers of known triplet-energy values were tested individually for activity in sensitizing the photodegradation of each of 23 radiolabeled pesticide chems.; 175 unlabeled pesticides were screened for photosensitizing activity against each of six 14C-labeled insecticide chems. The conversion of aldrin, dieldrin, and endrin to photoisomeric derivs. is accelerated by many compds. of high triplet-energy state. Some aromatic amines sensitize the photodecompn. of DDT and several chlorinated cyclodienes, possibly by formation of charge transfer complexes. Anthraquinone shows the broadest spectrum of activity of the sensitizers tested in combination with organophosphorus compds., methylcarbamates, pyrethroids, rotenone, dinitrophenol derivs., piperonyl butoxide, and 2,4-D. There is a possibility of a photosensitizing pesticide chem. markedly altering the persistence of another pesticide chem., but these interactions of a photosensitizing nature occur with only a few combinations of pesticides studied. However, LC50's decrease in time in a manner that depends both on the chem. and on the organism. DEBtox is an existing approach to analyze toxicity data in time, based on hazard modeling (the internal concn. increases the probability to die). However, certain chems. elicit their response through (irreversible) interaction with a specific receptor, such as inhibition of acetylcholinesterase (AChE). Effects therefore do not

solely depend on the actual internal concn., but also on its (recent) past. In this paper, the DEBtox method is extended with a simple mechanistic model to deal with receptor interactions. We analyzed data from the literature for organophosphorus pesticides in guppies, fathead minnows, and springtails. Overall, the obsd. survival patterns do not clearly differ from those of chems. with a less-specific mode of action. However, using the receptor model, resulting parameter ests. are easier to interpret in terms of underlying mechanisms and reveal similarities between the various pesticides. We obsd. that the no-effect concn. estd. from the receptor model is basically identical to the value from std. DEBtox, illustrating the robustness of this summary statistic. 597. Jancsok, Pal T., Clijmans, Luc, Nicolai, Bart M., and De Baerdemaeker, Josse (2001). Investigation of the effect of shape on the acoustic response of `conference' pears by finite element modelling. *Postharvest Biology and Technology* 23: 1-12.
Chem Codes: Chemical of Concern: PSM Rejection Code: MODELING.

The impulse response method is often used to measure firmness of spherical fruits. In this method the fruit is excited using an impact hammer and the response signal is captured using a microphone. This vibration response signal is subsequently analysed and related to the firmness of the fruit. In our work the effect of the shape of pears on their resonant frequencies is investigated using finite element (FE) modal analysis. Fifty differently shaped 3D FE meshes of `Conference' pears were generated using a geometrical modelling system. The FE model was validated, and found to be sufficiently accurate. The length/maximal diameter (L/D) ratio and the Fourier descriptors were used as shape descriptors. A strong linear relationship (r2>0.84) was found between the third normalised Fourier descriptor (F3) and the resonant frequencies. A weak linear relation was detected using the L/D and the other normalised Fourier descriptors. A simulation of firmness measurements based on the calculated resonant frequency values was carried out to estimate the Young's (E) modulus of the pear as a measure of its firmness. The estimated error with these simulations was found to be 31.44, 8.02 and 3.82% if the bending, the compression and the oblate-prolate modes were measured and the L/D was used as a shape descriptor. If F3 was used, the following error values were found: 6.0% for the bending, 3.39% for compression and 3.38% for the oblate-prolate modes. The results of this study may help in the development of a non-destructive firmness sensor for non-spherical fruits. 598. Jankovic, I. and Barnes, R. (1999). Three-dimensional flow through large numbers of spheroidal inhomogeneities. *Journal of Hydrology* 226: 224-233.
Chem Codes: Chemical of Concern: PSM Rejection Code: CHEM METHODS.

An implicit analytic solution is presented for three-dimensional (3D) groundwater flow through a large number of non-intersecting spheroidal inhomogeneities in the hydraulic conductivity. The locations, dimensions, and conductivity of the inhomogeneities may be arbitrarily selected. The specific discharge potential due to each inhomogeneity is expanded in a series that satisfies the Laplace equation exactly. The unknown coefficients in this expansion are related to the coefficients in the expansion of the combined specific discharge potential from all other elements. Using a least-squares formulation for the boundary conditions, a superblock approach, and an iterative algorithm, solutions can be obtained for a very large number of inhomogeneities (e.g. 10,000) on a personal computer to any desired precision, up to the machine's limit. Such speed and precision allows the development of a numerical laboratory for investigating 3D flow and convective transport. 599. Jarvis, A. W., Lubbers, M. W., Waterfield, N. R., Collins, L. J., and Polzin, K. M. (1995). Sequencing and analysis of the genome of lactococcal phage c2: International Dairy Lactic Acid Bacteria

Conference. *International Dairy Journal* 5: 963-976.
Chem Codes: Chemical of Concern: PSM Rejection Code: BACTERIA.

The genome of lactococcal prolate-headed phage c2 was sequenced and found to be 22163 bp in length. Early and late genes were identified by transcription mapping. Six putative early promoters and a divergently orientated late promoter were identified. The transcription sites of the early promoters were mapped and the sizes of several transcripts were determined by Northern hybridization. The early region (approximately 6 kb) contained 22 open reading frames (ORFs), and the late region (approximately 16 kb) contained 17 ORFs. N-terminal amino acid sequences were determined for three major and eight minor phage structural proteins, and the gene sequences identified in the late region. Immunogold electron microscopy was used to distinguish major head and tail proteins, and the tail adsorption protein. The late region also contained the phage lysin gene which was cloned and expressed in Escherichia coli. A 521 bp sequence located between the early and late regions was shown to act as an origin of replication in Lactococcus lactis when cloned into the vector pVA891, indicating that the cloned sequence contains an ori. The cos region was elucidated, and the termini of the genome were shown to be complementary non-symmetrical 9 base single-stranded 3' extended DNAs. A putative terminase binding site was identified.

600. Jauniaux, E., Gulbis, B., and Burton, G. J. (The Human First Trimester Gestational Sac Limits Rather Than Facilitates Oxygen Transfer to the Foetus--a Review. *Placenta. 2003, apr; 24 suppl a:s86-93. [Placenta]: Placenta*.
Chem Codes: Chemical of Concern: PSM Rejection Code: HUMAN HEALTH.

ABSTRACT: Oxygen (O2) free radicals are a potential teratologic threat to the foetal tissues and are known to be involved in the pathophysiology of common human pregnancy disorders such as miscarriage and pre-eclampsia. During the first two months of human gestation, the placenta surrounds the whole gestational sac, the villi contain only a few capillaries located mainly within the centre of the mesenchymal core, the trophoblastic layer is twice the thickness it will be in the second trimester, the foetal red cells are nucleated and the exocoelomic cavity (ECC) occupies most of the space inside the gestational sac. The ECC contains no oxygen transport system, but anti-oxidant molecules that may provide additional protection to the embryo from oxidative damage are present. Ultrasound and anatomical studies have also demonstrated that the intervillous circulation starts in the periphery of the placenta at around 9 weeks of gestation, and that it becomes continuous and diffuse in the entire placenta only after 12 weeks. Overall, these anatomical features provide indirect evidence that the architecture of the human first trimester gestational sac limits foetal exposure to O2 to what is strictly necessary for its development. These results are in agreement with the concept that the placenta and foetus develop in a physiologically low O2 environment and that its metabolism must be essentially anaerobic. Because of these anatomical arrangements, different nutritional pathways to those operating during most of pregnancy must serve the first-trimester foetus. Up to 9 weeks of gestation, foetal nutrition appears to depend on uterine glandular secretions that are delivered into the intervillous space, supplemented by maternal plasma proteins and other molecules that may percolate through the trophoblastic shell. These molecules diffuse through, or are transported by, the trophoblast of the villi and the chorionic plate into the ECC. From here they are absorbed by the secondary yolk sac (SYS), in which the extraembryonic circulation is probably first established. At the end of the first trimester, the SYS and two-thirds of the placental mass degenerate, and the ECC is progressively obliterated by the enlarging amniotic cavity. The trophoblastic plugs occluding the utero-placental arteries are gradually dislocated, allowing maternal blood to flow into the intervillous space, and the uterine glands involute. These major anatomical transformations modify considerably the spatial relationships between the maternal tissues and the developing embryo, and, consequently, the materno-embryonic exchange pathways. Overall the comparison of morphological features with physiological findings reveals that the architecture of the human first trimester gestational sac is designed to limit foetal exposure to oxygen to that which is strictly necessary for its development, and that during early pregnancy alternative nutritional pathways are in use.

It entails extn. of the target pesticides from 1-L water samples by solid-phase extn. (SPE), then gas chromatog. (GC) with large-vol. (40 mL) injection. Filtered surface water, from the St Lawrence River in Canada and the River Loire and its tributaries in France, was extd. on cartridges filled with 500 mg Carbopack B (120-400 mesh). Anal. was performed by gas chromatog. with a thermionic specific detector (GC-TSD) and a mass spectrometric (MS) detector. Overall percentage recoveries were satisfactory (>70%) for all target pesticides, with precision error <10%. Detection limits were between 0.5 and 4 ng L-1. Chem Codes: Chemical of Concern: PSM Rejection Code: CHEM METHODS.

ABSTRACT: PESTAB. Studies on the determination of organophosphorus insecticides in the atmosphere are reviewed. Spectrophotometric methods were described for various compounds, including parathion, phthalophos (phosmet), phosalone, dichlorvos, chlorophos (trichlorfon), demeton-methyl, oxydemeton-methyl, dimethoate, mecarbam, morphothion, demeton, thiometon, prothoate, vamidothion, thionazin, trichlorfon, demephion, butonate, dicofol, methyl parathion, Di-Syston (disulfoton), octamethyl, and phosphamidon. Also described were gas chromatographic techniques for determining Birlane EC 24 (chlorfenvinphos), diazinon, ethion, fenitrothion, and thiometon levels in the atmosphere. In contrast to the spectrophotometric and gas-chromatographic methods, enzymatic methods are able to provide information on both the concentration and toxicity of the studied compound in an atmosphere sample. Tests on percentage inhibition of (horse serum) cholinesterase activity, based on a modification of Giang and Hall's method, are described for Ekatox 20 (thiometon), E 605 (parathion), and Potasan.

605. Jenkins, T. F. and Palazzo, A. J. (Wastewater Treatment by a Prototype Slow Rate Land Treatment System. *Govt reports announcements & index (gra&i), issue 06, 1982*.
Chem Codes: Chemical of Concern: PSM Rejection Code: FATE.

ABSTRACT: TD3: Six slow rate land treatment prototypes, three containing a Windsor sandy loam and three containing Charlton silt loam, were studied from June 1974-May 1980. The systems were spray irrigated with either primary or secondary wastewater at application rates ranging from 2.5 cm/wk to 15 cm/wk. Application schedules were also varied. The performance of forage grasses was studied to determine the yield and nutrient uptake under the various application regimes. The results indicate that, on a mass basis, an average of 91% of the nitrogen (N) applied could be attributed to either plant uptake or percolation of soluble N, mainly nitrate. Nitrate concentrations in the percolate were found to correlate with N loading rate. An N loading rate of 800 kg/ha resulted in a mean concentration of about 10 mg of NO3-N in the percolate. Plant uptake of N was linearly related to N loading rate at loading rates less than 800 kg/ha. In this range, plant uptake accounted for about 60% of the N applied. Mean phosphorus

At identical concns., oxon analogs of these insecticides had no effect on proctolin or neural responses in the hindgut while a phosphonate insecticide, EPN, had a long-lasting potentiating action on contraction. The present investigation identifies a new site of organophosphorus insecticide action that may be a useful model system for the design and testing of pesticides that interfere with peptidergic transmission. 607. Jenny, Matthew J., Warr, Gregory W., Ringwood, Amy H., Baltzegar, David A., and Chapman, Robert W. (2006). Regulation of metallothionein genes in the American oyster (Crassostrea virginica): Ontogeny and differential expression in response to different stressors. *Gene* 379: 156-165.
Chem Codes: Chemical of Concern: PSM Rejection Code: IN VITRO.

Metallothioneins (MTs) are typically low molecular weight (6-7 kDa), metal-binding proteins with characteristic repeating cysteine motifs (Cys-X-Cys or Cys-Xn-Cys) and a prolate ellipsoid shape containing single [alpha]- and [beta]-domains. While functionally diverse, they play important roles in metals homeostasis, detoxification and the stress response. The present study, combined with previous observations (e.g., Jenny et al., Eur. J. Biochem. 2005; 271:1702-1712) defines an unprecedented diversity of MT primary structure and domain organization in the American oyster, Crassostrea virginica. Two novel molluscan MT families are described. One of these (CvMT-III) is characterized by the presence of two [beta]-domains and the absence of [alpha]-domains. This family exhibits constitutive expression during larval development and is the dominant CvMT isoform expressed in larvae. CvMT-III displays low basal levels of expression in adult tissues and only moderate responsiveness to metal challenges in both larvae and adults. A second novel MT isoform (CvMT-IV) was isolated from hemocytes by subtractive hybridization techniques following a 4-hour immune challenge with heat-killed bacteria (Vibrio, Bacillus, Micrococcus spp. mixture). Based on conservation of the cysteine motifs, this isoform appears to be a sub-family related to the molluscan [alpha][beta]-domain MTs. A series of amino acid substitutions has resulted in four additional cysteines which give rise to a Cys-Cys motif and three Cys-Cys-Cys motifs. Northern blot analyses demonstrate that CvMT-IV is down-regulated upon sterile wounding and immune challenge, displays moderate expression in larvae and adults and differential gene induction in response to metals exposure. Citations: Wilkinson, C; Regulatory Toxicology and Pharmacology 2000, 31, 30 The aim of the study is to evaluate the potential cumulative effects of organophosphorus and carbamate pesticides that act through a common mechanism of toxicity, and to assess the long- and short-term risks for the Danish population. The intake ests. are based on dietary intake data collected in the Danish nation-wide food consumption survey in 1995. The pesticide data are based on the Danish pesticide residue-monitoring program from 1996-2001. The amt. of 35 organophosphorus pesticides and carbamates were included in the cumulative risk assessment. Processing factors, such as redn. of pesticide levels by rinsing and peeling, were applied in the exposure assessment. The \"Toxicity Equivalence Factor\" (TEF) approach was used to normalize the toxicity of the different organophosphorus and carbamate pesticides. Cumulative chronic exposure of organophosphorus and carbamates pesticides via fruit, vegetables and cereals is for adults 0.8-2% of the Acceptable Daily Intake (ADI) in chlorpyrifos equiv., and 0.03-11% of the ADI in methamidophos equiv.; and for children 2-5% of the ADI in the chlorpyrifos equiv., and 0.07-27% of the ADI in methamidophos equiv. Neither Acute Ref. Dose (ARfD) nor ADI was exceeded for any of the compds. studied. The results indicate that the Danish population is neither exposed to any cumulative chronic risk, nor at risk of acute exposure, from consumption of organophosphorus and carbamate pesticides from fruit, vegetables and cereals. 609. Jensen, E. S. (1994). Leaching in Small Lysimeters of Nitrate Derived From Nitrogen-15-Labeled Field Pea Residues. *Journal of Environmental Quality, 23 (5) pp. 1045-1050, 1994.*
Chem Codes: Chemical of Concern: PSM Rejection Code: SURVEY.

ISSN: 0047-2425
Abstract: Field pea (Pisum sativum L.) crop residues labeled with superior 1 superior 5N were incorporated during September in small monolith lysimeters of a sandy loam soil. The leaching of superior 1 superior 5N-labeled and nonlabeled NO inferior 3 to below 45 cm was studied during the subsequent 2 to 3 yr comparing (i) planted vs. unplanted soil and (ii) with and without pea residue incorporation. The peak flux of labeled NO inferior 3-N from uncropped soil occurred in December. During the first leaching period (September-April), 15 and 7% of the residue N was

recovered as NO inferior 3 in the percolate in the two experiments, corresponding to 18 and 13% of total NO inferior 3-N in the percolates, respectively. The difference observed in leaching of labeled N in the two experiments was mainly due to a much higher drainage volume in the first experiment. The different residue particle sizes, 10 mm or less than 3 mm, used in the two experiments may have influenced the immobilization-mineralization of N in the soil differently and consequently the potential for NO inferior 3 leaching. Pea residue N constituted 10 to 15% and 5% of total NO inferior 3-N leached from unplanted soil in the second and third leaching periods, respectively. Incorporating the ground pea residues reduced the total amount of NO inferior 3 leached by 15% during the first leaching period, indicating that the pea residue may be an important factor in controlling leaching losses. Ryegrass (Lolium perenne L.) established on lysimeters at the time of residue incorporation reduced the total leaching of N in the first leaching period by 15%, but in the second and third leaching period grass eliminated NO inferior 3 leaching completely.

Abstract: There exist many taxonomic uncertainties in the genus Actinidia Lindl. as to the circumscription of sections and treatment of closely related species because of natural interspecific crossing. Little has been attempted to use micromorphological characters to address the problems. Pollen morphology of 21 species, 6 varieties and 4 interspecific hybrids (F<inf>1</inf>) of the genus Actinidia was studied using SEM. A detailed description of the pollen grains was presented and a key to the species of the genus was given based on the pollen morphology observed. The results were summarized as follows: (1) The pollen grains are mainly prolate to subspheroidal in shape, and there were less distinct interspecific differences in the shape than those in size and ornamentation. (2) Most species introduced from the wild have three colporate apertures rather than three colporoid apertures as previously reported, the reason for which could be presumed that the pollen materials observed were harvested from specimens collected from different places with different habitats and that the plants might have undergone various crossings in the wild. (3) The pollen grains of interspecific hybrids were hollow and infertile, which may be due to the different ploidy levels between the parental species, a phenomenon common in the genus Actinidia . (4) The pollen of cultivated staminate varieties was compared with that of the wild types, and the ornamentation became finer than that of the later ones. This characteristic was presumed to be an important evolutionary trait beneficial to pollination in dioecious plants, a phenomenon which is worthy of further study. (5) The pollen size of male plant individuals is found to be somewhat correlated with the fruit size, a phenomenon which may be helpful for early selection of hybrids. 28 refs.

Legumin, a protein isolated from pea seeds (Pisum sativum) has been examined by physicochemical methods, and a molecular weight of 398,000 +/- 15,000 has been obtained in reasonable agreement with some previous estimates. It is not possible to decide between a prolate or oblate ellipsoid of low axial ratio as a suitable hydrodynamic model; both are in reasonable agreement with the indications of electron microscopy. The rotational relaxation time deduced from depolarization of fluorescence measurements of conjugates of the protein with fluorescent dyes is six times smaller than the minimum calculated for the relaxation time of the above models. Intramolecular freedom of rotation must be responsible. Detailed examination of depolarization measurements indicates that the relaxation time changes more rapidly with temperature than the usual linear dependance on [eta]/T, and certain irreversible features are apparent above 50 [degree sign]C. The relaxation time also decreases as the pH deviates from the isoelectric point in the absence of any molecular weight changes. At low urea concentration, the relaxation time increases slightly, probably because of urea absorption and interference with internal rotation. At higher concentrations of urea, in the presence of guanidine hydrochloride, and at extremes of pH where molecular weight changes are involved, further decreases in relaxation time are involved.

Chem Codes: Chemical of Concern: PSM Rejection Code: FATE.

ABSTRACT: BIOSIS COPYRIGHT: BIOL ABS. Losses of total recoverable potassium (K) were measured in runoff and percolate waters from field lysimeter plots of Blount silt loam (fine, illitic, mesic Aeric Ochraqualfs) from May 1972 through April 1974. Six plots were irrigated annually with digested sewage sludge, while another six plots which had been treated with a complete fertilizer were irrigated with well water. Each year all plots were fertilized with KCl in amounts that supplied 269 kg K ha-1 prior to the preparation of a seedbed for corn (Zea mays L.). for the 2 yr of record, combined K losses in runoff and drainage waters from sludge-treated plots averaged 41.9 and 8.2 kg ha-1, respectively. For the same years, losses from plots irrigated with well water averaged 23.3 and 10.5 kg K ha-1 in runoff and drainage waters, respectively. The differences between treatments within each year were not significant, but they were significant between years within treatment. Large K losses occurred in runoff during hea

615. Josephsen, Jytte and Klaenhammer, Todd (1990). Stacking of three different restriction and modification systems in Lactococcus lactis by cotransformation. *Plasmid* 23: 71-75.
Chem Codes: Chemical of Concern: PSM Rejection Code: BACTERIA.

Four plasmids encoding restriction and modification (R/M) systems are described that are different in the specificity of their restrictive activity toward the small isometric phage p2 and prolate phage c2. The R/M plasmids were cotransformed into Lactococcus lactis MG1363 with pVS2, encoding resistance to chloramphenicol and erythromycin, to indicate successful transformation events. Analysis of cotransformants showed that three different R/M plasmids could be combined in L. lactis MG1363. The efficiency at which phage plaqued on the transformants decreased as the number of R/M plasmids increased. Some plasmid combinations were unstable suggesting replicon incompatibility.

Chem Codes: Chemical of Concern: PSM Rejection Code: BACTERIA.

Streptococcus lactis subsp. cremoris W56 (S. cremoris W56) is a strain partially resistant to phage attack. Derivatives which had lost either plasmid pJW563 or pJW566 no longer expressed the restriction and modification systems encoded by these plasmids. Genetic evidence for the correlation between the plasmids and the R/M systems was obtained by transformation. In addition, a third R/M system was discovered among the transformants and was shown to be encoded by pJW565. Thus, genetic evidence for at least 3 distinct R/M systems encoded by plasmids in S. cremoris W56 is presented. One of the R/M-systems showed stronger restriction of the isometric phage p2 than of the prolate phage c2. The other two systems restricted both classes of phages with equal efficiencies. Chem Codes: Chemical of Concern: PSM Rejection Code: HUMAN HEALTH.

ABSTRACT: BIOSIS COPYRIGHT: BIOL ABS. The objective of the study was to corroborate or refute the hypothesis that farmers having a high intake of organic grown commodities have a high semen quality due to their expected lower level of dietary pesticides intake. Food frequency data and semen were collected from 256 farmers (171 traditional farmers and 85 organic farmers, overall participation rate: 32%) who were selected from central registers. Each farmer delivered one semen sample before the spraying season started. The farmers wer ual mean intake of single commodities, such as rice, potato, and pork meat. The current individual dietary intake of 40 pesticides was estimated using food frequencies and generalized serving size data in combination with data on pesticide concentrations in food commodities as obtained from the National Danish Food Monitoring Program. The estimated pesticide intake was significantly lower among farmers of group H, but for all three groups of farmers the average dietary intake of 40 pesticides wa The group of men without organic food intake had a significant lower proportion of morphologically normal spermatozoa, but in relation to 14 other semen parameters no significant differences werefound between the groups. Intake of 40 individual pesticides was correlated with four semen parameters (concentration, percentage dead spermatozoa, percentage normal sperm heads, and motility (VCL)). Five significant correlations (p value 0.01) were found among the 160 comparisons in relation to percent sion, the estimated dietary intake of 40 pesticides did not entail

a risk of impaired semen quality, but precautions should be taken when generalizing this negative result to populations with a higher dietary exposure level or an intake of other groups of pesticides.

The program basis is a random sample control supplemented with a target control. The objectives of the control are to monitor consumer exposure to health hazards and to enforce national and European Community regulations. The Danish Veterinary and Food Administration is responsible for establishing methods, data manipulation, and evaluation, but actual analyses are performed at 4 regional labs. In addn. to a description of the Danish National Pesticide Monitoring Program on food, the effects of lowering the reporting limits are discussed. Pesticides included are those in current use as well as chlorinated pesticides like lindane, DDT, and HCB, occurring in food now primarily as a result of environmental contamination. Commodities analyzed are fruits, vegetables, cereals, bran, fish, and animal products such as meat, butter, cheese, fat, and eggs. In fruits and vegetables, residues were detected in 10% of 2515 samples, with higher incidences of detection for foreign commodities. Violation rate was 0.6%. In food of animal origin, low levels of organochlorine pesticides were detected in most fish samples and in more than half of the animal product samples. However, no results exceeding max. residue limits were found. No residues of organophosphorus pesticides were detected in the 231 meat samples analyzed. Chem Codes: Chemical of Concern: PSM Rejection Code: CHEM METHODS.

The hemin moiety of horseradish peroxidase (donor: hydrogygen-peroxide oxidoreductase, EC 1.11.1.7) was removed and the apoprotein reconstituted with the fluorescent protoporphyrin IX. Steady-state and time-resolved fluorescence properties of the HRP(desFe) adduct were examined; the multifrequency phase and modulation method was utilized for lifetime and dynamic polarization studies. The emission spectrum of HRP(desFe) had maxima at 633 and 696 nm. The lifetime of this emission was characterized by a single exponential decay of 16.87 ns at 22[degree sign]C. Debye rotational relaxation times for HRP(desFe) were determined using both static (Perrin plot) and dynamic (differential phase and modulation fluorometry) methods; these two approaches gave values of 96 and 86 ns, respectively. A spherical protein of HRP's molecular weight and partial specific volume would be expected to have a Debye rotational relaxation time, at 22[degree sign]C, in the range of 50 to 60 ns, depending upon the extent of hydration. Hence our results indicate that HRP(desFe) is asymmetric; the global rotational relaxation times observed are consistent with those of a prolate ellipsoid with an axial ratio of 3:1. The 1st was an eight-year-old 30,000 L concrete-lined pit where over 50 kg of more than 40 different pesticides had been deposited. The 2nd was a two-year-old 90,000 L polyethylene-lined pit where 150 kg of 24 different pesticides had been deposited. The pesticide concns. in the soil and liq. samples taken from these pits showed extreme variations which necessitated collecting and compositing samples from many different points to est. the av. pesticide concns. and their change with time. Water, soil and air samples were also collected and analyzed to evaluate the possible contamination of the surrounding environment. Conclusions from these investigations are: 1) pit disposal systems are effective in contg. many pesticides to the extent that release to surrounding air and water is insignificant; 2) possible environment effects can be established by avoiding the extreme difficulties assocd. with solid samples and taking only liq. samples for analyses; 3) pit disposal systems are effective for pesticides as well as other org. chem. Chem Codes: Chemical of Concern: PSM Rejection Code: FATE.

ABSTRACT: PESTAB. A summary of results of 50 yr of experimentation of plant-soil systems is presented. Among the most important conclusions drawn from over 1.5 million soil and 190,000 crop analyses is that the lysimeter trial is an accurate aid for establishing nutrient balances for the plant soil system. Among factors influencing transportation of substances into the soil are environmental considerations (weather, soil type, and vegetative cover) and the nature of the nutrient. Nitrogen and calcium are easily displaced and leached out of the soil, while the mobility of Mg and K is considerably less. Phosphorous is the least mobile primary nutrient in the soil, most of it is removed by the crop stand. Experiments with pesticides have shown that hormone-like weed killers such as 2,4-D, 2,4,5-T, and MCPA were not present in any sample percolate. Other herbicides (pyrazon, fluochloralin, and chlormequate chloride) were likewise not measurable at a depth of 1 m at a detection limit of 0.002 ppm.

Index Terms: Chromatography (of imidan and its degrdn. products)
CAS Registry Numbers: 732-11-6; 732-11-6D Role: BIOL (Biological study) (TLC of); 85-41-6; 88-97-1; 88-99-3; 118-29-6; 3735-33-9 Role: BIOL (Biological study) (imidan degrdn. product, TLC of) A 2-phase TLC method (silica gel-Plaster of Paris; 9:1 CHCl3-C6H6 and 1:1 CHCl3-EtOH solvent systems) was used for sepg. imidan [732-11-6] and its degrdn. products: imidoxon [3735-33-9], N-hydroxymethyl phthalimide [118-29-6], phthalimide [85-41-6], phthalamic acid [88-97-1], and phthalic acid [88-99-3]. The CHCl3-C6H6 system was used for the resoln. of the 1st 4 compds. and the 2nd solvent system (CHCl3-EtOH) for the other 2 compds. TLC development in an I chamber gave spots colored differently (brown, yellow, colorless). [on SciFinder (R)] 0031-6148 TLC/ imidan/ degrdn/ product
